# List of Figures

1.1	The particles of the Standard Model. . . . .	10
1.2	Summary of how Standard Model particles interact with other Standard Model particles. . . . .	11
1.3	This figure shows the three dominant QCD interactions. From Ref. [14] . . . . .	17
1.4	Strength of the U(1), SU(2), and SU(3) gauge couplings as a function of the energy scale of the interaction ( $Q$ ). From Ref. [10] . . . . .	18
2.1	A comparison of cross section measurements at $\sqrt{s} = 7, 8, 13$ TeV from ATLAS compared to theoretical measurements. From Ref. [5]	22
3.1	Cartoon of RS Bulk Model . . . . .	24
4.1	Scaling of cross sections with $\sqrt{s}$ . Natasha: write more here . . . . .	31
4.2	LHC Layout. Natasha write more . . . . .	33
4.3	LHC Accelerator. Natasha write more . . . . .	35
5.1	Big picture layout of ATLAS detector. Natasha: write more . . . . .	38
5.2	Big picture layout of ATLAS detector. Natasha: write more . . . . .	38
5.3	A simplified schematic of how different particles interact and are detected within ATLAS. . . . .	39
5.4	Layout of ATLAS Inner Detector . . . . .	41
5.5	Layout of ATLAS ID Barrel System. . . . .	42
5.6	Overview of ATLAS electromagnetic and hadronic calorimeters. . . . .	46

5.7	Schematic of ECAL . . . . .	47
5.8	Schematic of HCAL . . . . .	47
5.9	Schematic of Muon Spectrometer [cite G35] . . . . .	50
5.10	Schematic of MDT chamber. [cite G35] . . . . .	51
5.11	Schematic of RPC chamber, which is used for triggering in the central region of the detector [cite G35]. . . . .	51
5.12	Schematic of TGC chamber, which is used for triggering in the muon end-cap region. [cite G35] . . . . .	52
5.13	Layout of ATLAS magnet systems. . . . .	53
6.1	Integrated luminosity for data collected from ATLAS from 2011 - 2018 . . . . .	57
6.2	Mean number of interactions per crossing for data collected from ATLAS from 2011 - 2018 . . . . .	58
6.3	This figure shows the breakdown of the muon reconstruction efficiency scale factor measured in $Z \rightarrow \mu\mu$ as a function of $p_T$ [4]. . . . .	62
6.4	[6] This diagram shows the calibration stages for EM jets. . . . .	65
6.5	The upper cut on $D_2$ (a) and jet mass window cut i.e. the upper and lower boundary of the mass (b) of the $W$ -tagger as a function of jet $p_T$ . Corresponding values for $Z$ -tagger are shown in (c) and (d). The optimal cut values for maximum significance are shown as solid markers and the fitted function as solid lines. Working points from $VV \rightarrow JJ$ [ATLAS-HDBS-2018-31-002] is also shown as dashed lines as a reference. Natasha reword? . . . . .	67
6.6	Natasha write caption . . . . .	67
7.1	RNN architecture. Natasha add caption . . . . .	75
7.2	RNN Score distribution for ggF and VBF signals and backgrounds. . . . .	76
7.3	ROC curve using k-fold validation for RNN. . . . .	77

7.4	Comparison of GGF Z' limits for different RNN score selections. The bottom panel shows the ratio of the upper limits set for different RNN cuts to the cut-based analysis. In this panel smaller numbers, indicate that the expected upper limit is smaller than the cut-based analysis, which is desired. . . . .	78
7.5	Event Categorization. Natasha write more. . . . .	81
7.6	Data MC comparison for the merged $WW$ HP TCR. The bottom panel shows the ratio of the difference between data and simulation to simulation. The red bands include the all systematic and statistical uncertainties on the background. . . . .	82
7.7	Data MC comparison for the merged $WW$ LP TCR. The bottom panel shows the ratio of the difference between data and simulation to simulation. The red bands include the all systematic and statistical uncertainties on the background. . . . .	83
7.8	Data MC comparison for the merged $WZ$ HP TCR. The bottom panel shows the ratio of the difference between data and simulation to simulation. The red bands include the all systematic and statistical uncertainties on the background. . . . .	84
7.9	Data MC comparison for the merged $WZ$ LP TCR. The bottom panel shows the ratio of the difference between data and simulation to simulation. The red bands include the all systematic and statistical uncertainties on the background. . . . .	85
7.10	Data MC comparison for the resolved $WW$ TCR. The bottom panel shows the ratio of the difference between data and simulation to simulation. The red bands include the all systematic and statistical uncertainties on the background. . . . .	86
7.11	Data MC comparison for the resolved $WZ$ TCR. The bottom panel shows the ratio of the difference between data and simulation to simulation. The red bands include the all systematic and statistical uncertainties on the background. . . . .	87

7.12 Selection acceptance times efficiency for the $W' \rightarrow WZ \rightarrow \ell\nu qq$ events from MC simulations as a function of the $W'$ mass for (a) Drell-Yan and (b) VBF production, combining the merged HP and LP signal regions of the $WW \rightarrow \ell\nu J$ selection and the resolved regions of the $WW \rightarrow \ell\nu jj$ selection. . . . .	88
7.13 Selection acceptance times efficiency for the $G \rightarrow WW \rightarrow \ell\nu qq$ events from MC simulations as a function of the $G$ mass for (a) Drell-Yan and (b) VBF production, combining the merged HP and LP signal regions of the $WW \rightarrow \ell\nu J$ selection and the resolved regions of the $WW \rightarrow \ell\nu jj$ selection. . . . .	89
7.14 The $E_T^{miss}$ distribution in MJCR for 2017 data in the electron channel(left), muon channel with W-boson pT < 150 GeV (center) and > 150 GeV (right). Multi-jet templates are calculated as remaining data components after excluding known MC . . . . .	91
7.15 Postfit Data/MC comparison of distributions of $E_T^{miss}$ , $m_T^W$ , lepton and neutrino $p_T$ , $m_{\ell\nu jj}$ , lepton- $\nu$ angular distance in the $WW$ electron channel. The MJ template is obtained from the pre-MJ-fit. . . . .	92
7.16 Postfit Data/MC comparison of distributions of $E_T^{miss}$ , $m_T^W$ , lepton and neutrino $p_T$ , $m_{\ell\nu jj}$ , lepton- $\nu$ angular distance in the $WW$ muon channel. The MJ template is obtained from the pre-MJ-fit. . . . .	93
7.17 Postfit Data/MC comparison of distributions of $E_T^{miss}$ , $m_T^W$ , lepton and neutrino $p_T$ , $m_{\ell\nu jj}$ , lepton- $\nu$ angular distance in the $WZ$ untag electron channel. The MJ template is obtained from the pre-MJ-fit. . . . .	94
7.18 Postfit Data/MC comparison of distributions of $E_T^{miss}$ , $m_T^W$ , lepton and neutrino $p_T$ , $m_{\ell\nu jj}$ , lepton- $\nu$ angular distance in the $WZ$ untag muon channel. The MJ template is obtained from the pre-MJ-fit. . . . .	95
7.19 Postfit Data/MC comparison of distributions of $E_T^{miss}$ , $m_T^W$ , lepton and neutrino $p_T$ , $m_{\ell\nu jj}$ , lepton- $\nu$ angular distance in the $WZ$ untag electron channel. The MJ template is obtained from the pre-MJ-fit. . . . .	96

7.20 Postfit Data/MC comparison of distributions of $E_T^{miss}$ , $m_T^W$ , lepton and neutrino $p_T$ , $m_{\ell\nu jj}$ , lepton- $\nu$ angular distance in the $WZ$ untag muon channel. The MJ template is obtained from the pre-MJ-fit.	97
7.21 Postfit Data/MC comparison of distributions of $E_T^{miss}$ , $m_T^W$ , lepton and neutrino $p_T$ , $m_{\ell\nu jj}$ , lepton- $\nu$ angular distance in the VBF $WW$ electron channel. The MJ template is obtained from the pre-MJ-fit.	98
7.22 Postfit Data/MC comparison of distributions of $E_T^{miss}$ , $m_T^W$ , lepton and neutrino $p_T$ , $m_{\ell\nu jj}$ , lepton- $\nu$ angular distance in the VBF $WW$ muon channel. The MJ template is obtained from the pre-MJ-fit.	99
7.23 Postfit Data/MC comparison of distributions of $E_T^{miss}$ , $m_T^W$ , lepton and neutrino $p_T$ , $m_{\ell\nu jj}$ , lepton- $\nu$ angular distance in the VBF $WZ$ electron channel. The MJ template is obtained from the pre-MJ-fit.	100
7.24 Postfit Data/MC comparison of distributions of $E_T^{miss}$ , $m_T^W$ , lepton and neutrino $p_T$ , $m_{\ell\nu jj}$ , lepton- $\nu$ angular distance in the VBF $WZ$ muon channel. The MJ template is obtained from the pre-MJ-fit.	101
8.1 The W/Z+jet systematics for the a) Merged ggF, b) Resolved ggF, c) Merged VBF, and d) Resolved VBF regions. The top subplot shows the nominal and variation distributions/bands, the middle shows the ratio of the two, and the final shows just the shape of the envelope (the final uncertainty).	107
8.2 The two-point generator comparison between Sherpa and MadGraph for the W/Z+jet samples in the a) Merged ggF, b) Resolved ggF, c) Merged VBF, and d) Resolved VBF regions. The normalization of the Madgraph sample is set to the Sherpa value to consider only shape effects. The bottom inlet shows the ratio of the two.	108
8.3 Ratio between the variations of generator (red) and hadronization (blue) variations for the Merged regime for $t\bar{t}$ sample.	109
8.4 Ratio between the variations of generator (red) and hadronization (blue) variations for the Resolved regime for $t\bar{t}$ sample.	109

8.5	Ratio between the variations of ISR up (red) and down (blue) variations for the Merged regime for $t\bar{t}$ sample. . . . .	110
8.6	Ratio between the variations of ISR up (red) and down (blue) variations for the Resolved regime for $t\bar{t}$ sample. . . . .	111
8.7	Ratio between the variations of FSR up (red) and down (blue) variations for the Merged regime for $t\bar{t}$ sample. . . . .	112
8.8	Ratio between the variations of FSR up (red) and down (blue) variations for the Resolved regime for $t\bar{t}$ sample. . . . .	112
9.1	The HVT signal mass resolution as a function of mass fit with a straight line in the Resolved ggF region (left) and VBF (right) region. . . . .	116
9.2	The HVT signal mass resolution as a function of mass fit with a straight line in the Merged ggF region (left) and VBF (right) region. . . . .	116
10.1	These plots show the measured $p_0$ value as a function of resonance mass for HVT Z' DY production. . . . .	122
10.2	These plots show the measured $p_0$ value as a function of resonance mass for HVT Z' VBF production. . . . .	123
10.3	These plots show the measured $p_0$ value as a function of resonance mass for HVT W' DY production. . . . .	124
10.4	These plots show the measured $p_0$ value as a function of resonance mass for HVT W' VBF production. . . . .	125
10.5	These plots show the measured $p_0$ value as a function of resonance mass for the RS Graviton DY production. . . . .	126
10.6	Ranked systematics and their fitted values for WW DY (right) and VBF (left) selections. . . . .	127
10.7	Ranked systematics and their fitted values for WZ DY (right) and VBF (left) selections. . . . .	128
10.8	Correlations between systematics for WW DY (right) and VBF (left) selections. . . . .	128

10.9 This figure shows the distribution of $m_{\ell\nu qq}$ in the DY WW control regions. . . . .	136
10.10 This figure shows the distribution of $m_{\ell\nu qq}$ in the DY WZ control regions. . . . .	137
10.11 This figure shows the distribution of $m_{\ell\nu qq}$ in the VBF WW control regions. . . . .	138
10.12 This figure shows the distribution of $m_{\ell\nu qq}$ in the VBF WZ control regions. . . . .	139
10.13 This figure shows the distribution of $m_{\ell\nu qq}$ in the GGF WW signal regions. . . . .	140
10.14 This figure shows the distribution of $m_{\ell\nu qq}$ in the GGF WZ Untag signal regions. . . . .	140
10.15 This figure shows the distribution of $m_{\ell\nu qq}$ in the GGF WZ Tag signal regions. . . . .	141
10.16 This figure shows the distribution of $m_{\ell\nu qq}$ in the VBF WZ Tag signal regions. . . . .	141
10.17 This figure shows the distribution of $m_{\ell\nu qq}$ in the VBF WZ Tag signal regions. . . . .	142
10.18 This figure shows theory, expected and observed limits for HVT $W'$ DY (left) and VBF (right) production. . . . .	142
10.19 This figure shows theory, expected and observed limits for HVT $Z'$ DY (left) and VBF (right) production. . . . .	143
10.20 This figure shows theory, expected and observed limits for RS Gravitons via DY production. . . . .	143
11.1 PDGID of the truth-level parton matched to the small-R jets passing the Resolved GGF WW Signal Region selections for the (a) Leading (b) Sub-Leading jets . These distributions are shown for 300, 500, and 700GeV Z' signals and the background. . . . .	147

11.2 The number of tracks in small-R jets in events passing the Resolved GGF WW Signal Region selections for the (a) Leading (b) Sub-Leading jets. These distributions are shown for 300, 500, and 700GeV Z' signals and the background. . . . .	147
11.3 The number of tracks in background small-R jets in events passing the Resolved GGF WW Signal region selection vs. $\ln(p_T)$ for (a)Leading (b) Sub-Leading jets. The best fit line for the distribution is also shown, as well as the percentage of jets that pass a cut of number of tracks $< 4 \times \ln(p_T) - 5$ . Note the number of total entries in these plots has been normalized to one. . . . .	148
11.4 The number of tracks in small-R jets in 300GeV Z' events passing the Resolved GGF WW Signal region selection vs. $\ln(p_T)$ for (a)Leading (b) Sub-Leading jets. The best fit line for the distribution is also shown, as well as the percentage of jets that pass a cut of number of tracks $< 4 \times \ln(p_T) - 5$ .Note the number of total entries in these plots has been normalized to one. . . . .	148
11.5 The number of tracks in small-R jets in 500GeV Z' events passing the Resolved GGF WW Signal region selection vs. $\ln(p_T)$ for (a)Leading (b) Sub-Leading jets. The best fit line for the distribution is also shown, as well as the percentage of jets that pass a cut of number of tracks $< 4 \times \ln(p_T) - 5$ .Note the number of total entries in these plots has been normalized to one. . . . .	149
11.6 The number of tracks in small-R jets in 700GeV Z' events passing the Resolved GGF WW Signal region selection vs. $\ln(p_T)$ for (a)Leading (b) Sub-Leading jets. The best fit line for the distribution is also shown, as well as the percentage of jets that pass a cut of number of tracks $< 4 \times \ln(p_T) - 5$ .Note the number of total entries in these plots has been normalized to one. . . . .	149

11.7 The number of tracks in leading small-R jets in background events passing the Resolved GGF WW Signal region selection vs. $\ln(p_T)$ for (a)Gluons (b) Quarks jets. The best fit line for the distribution is also shown, as well as the percentage of jets that pass a cut of number of tracks $< 4 \times \ln(p_T) - 5$ .Note the number of total entries in these plots has been normalized to one. . . . .	150
11.8 ROC Curve for Quark and Gluon Tagging with a cut on the number of tracks that depends on the $\ln(p_T)$ . . . . .	150
11.9 The top panel shows the distribution of $m_{lvqq}$ with and without quark gluon tagging. The middle panel shows the ratio of the signals and backgrounds with and without quark gluon tagging. The bottom panel shows the change in $S/\sqrt{B}$ with quark gluon tagging. . . . .	151
13.1 The top panel shows the distribution of $m_{lvqq}$ with and without requiring jets to be true quarks. The middle panel shows the ratio of the signals and backgrounds with and without requiring jets to be true quarks. The bottom panel shows the change in $S/\sqrt{B}$ when requiring jets to be true quarks. . . . .	159
13.2 Unfolded and extracted $n_C$ qg dstbs. . . . .	160
13.3 PDGID of the truth-level parton matched to the small-R jets passing the Resolved GGF WW Signal Region selections for the (a) Leading (b) Sub-Leading jets . These distributions are shown for 300, 500, and 700GeV Z' signals and the background. . . . .	161
13.4 These figures show the impact of the uncertainties on the number of tracks in the leading jet in the sum of the background sample in the Resolved GGF WW SR (a) tracking efficiency (b) fake (c) PDF (d) ME (e) unfolding uncertainties. . . . .	162

# List of Tables

1.1	Representations of the SM fermions under $SU(3)_C \times SU(2)_L \times U(1)_Y$ gauge symmetry group. $SU(2)_L$ gauge transformations allow one to go between rows and $SU(3)_C$ transformations allow one to go between columns in these fermion representations. [REWORD]	9
7.1	The list of triggers used in the analysis. . . . .	72
7.2	Summary of selection criteria used to define the signal region (SR), $W$ +jets control region ( $W$ CR) and $t\bar{t}$ control region ( $t\bar{t}$ CR) for merged 1-lepton channel. . . . .	80
7.3	The list of selection cuts in the resolved analysis for the $WW$ and $WZ$ signal regions (SR), $W$ +jets control region (WR) and $t\bar{t}$ control region (TR). . . . .	81
7.4	Definitions of “inverted” leptons used in multijet control region . .	91
7.5	Fit validation result in WCRs for 2015+16 data. The fit is done in various WCRs, in order to obtain the corresponding scale factors for MJ templates: ggF resolved WCR for the $WW \rightarrow lvqq$ selection, ggF resolved untagged WCR for the $WZ \rightarrow lvqq$ selection, ggF resolved tagged WCR for the $WZ \rightarrow lvqq$ selection, VBF resolved WCR for the $WW \rightarrow lvqq$ selection, and VBF resolved WCR for the $WZ \rightarrow lvqq$ selection. Post-fit event yields for electroweak processes and MJ contributions are shown. The SF column shows the corresponding normalization scale factors for electroweak processes from the fit. R.U. stands for relative uncertainty. . . . .	102

10.1	Expected and Measured for DY $WW$ $W+\text{jets}$ , $t\bar{t}$ control regions and signal regions. . . . .	129
10.2	Expected and Measured for DY $WZ$ $W+\text{jets}$ , $t\bar{t}$ tag and untag control regions. . . . .	130
10.3	Expected and Measured for DY $WZ$ $W+\text{jets}$ , $t\bar{t}$ tag and untag signal regions. . . . .	131
10.4	Expected and Measured for VBF $WW$ $W+\text{jets}$ , $t\bar{t}$ control regions and signal regions. . . . .	132
10.5	Expected and Measured for VBF $WZ$ $W+\text{jets}$ , $t\bar{t}$ control regions and signal regions. . . . .	133
10.6	Fitted background normalizations for $t\bar{t}$ and $W+\text{jets}$ backgrounds for the DY $WW$ analysis region. . . . .	134
10.7	Fitted background normalizations for $t\bar{t}$ and $W+\text{jets}$ backgrounds for the DY $WZ$ analysis region. . . . .	134
10.8	Fitted background normalizations for $t\bar{t}$ and $W+\text{jets}$ backgrounds for the VBF $WW$ analysis region. . . . .	134
10.9	Fitted background normalizations for $t\bar{t}$ and $W+\text{jets}$ backgrounds for the VBF $WZ$ analysis region. . . . .	135

## Abstract

Search for  $WW$  and  $WZ$  resonance production in  $\ell\nu qq$  final states in  $pp$  collisions at  $\sqrt{s} = 13$  TeV with the ATLAS detector

by

Natasha Woods

This thesis reviews a search for  $WW$  and  $WZ$  resonance production using data from  $pp$  collisions at  $\sqrt{s} = 13$  TeV using the ATLAS detector, corresponding to an integrated luminosity of  $139 \text{ fb}^{-1}$ . Diboson resonances are predicted in a number of Standard Model (SM) extensions, such as Extended Gauge Models, Extra dimensions, and technicolor models. This search looks for resonances where one  $W$  boson decays leptonically and the other  $W$  or  $Z$  boson decays hadronically. This search is sensitive to diboson resonance production via vector-boson fusion as well as quark-antiquark annihilation and gluon-gluon fusion mechanisms. No significant excess of events is observed with respect to the Standard Model backgrounds. As the dominant backgrounds in this search contain gluons, classifying jets as quark or gluon initiated would make this analysis more sensitive to new physics. Towards this end, this thesis considers the prospects for adding a quark gluon tagger based on the number of tracks in jets and reviews the calibration of the number of tracks in jets.

A loving dedication.

## Part I

<sup>3</sup>

# Theoretical Motivation

<sup>4</sup> **Chapter 1**

<sup>5</sup> **The Standard Model of Particle  
6 Physics**

<sup>7</sup> **1.1 Introduction**

<sup>8</sup> By determining the dynamics of the most elementary degrees of freedom, par-  
<sup>9</sup> ticle physics hopes to uncover the fundamental laws of the universe. The definition  
<sup>10</sup> of elementary has evolved through time and currently refers to matter and force  
<sup>11</sup> mediating particles: fermions and bosons, respectively. The Standard Model of  
<sup>12</sup> Particle Physics (SM) describes the quantum behavior of three of the four funda-  
<sup>13</sup> mental forces: weak, strong, and electromagnetic, via boson and fermion interac-  
<sup>14</sup> tions. Gravity is not included in the SM and still under investigation.

<sup>15</sup> **1.2 Quantum Field Theory**

<sup>16</sup> In the SM, forces (and particles) are represented as fields. In this context,  
<sup>17</sup> fields are mathematical objects that define a tensor (e.g. scalar, vector, etc) at  
<sup>18</sup> every point on a manifold, here the manifold is space-time. These fields obey laws

<sup>19</sup> dictated by Quantum Field Theory (QFT). Particles arise naturally in QFT as  
<sup>20</sup> quantized field excitations localized in spacetime.

<sup>21</sup> According to Noether's theorem, symmetries of a field give rise to conserved  
<sup>22</sup> quantities (e.g. time-translation invariance leads to energy conservation). Often  
<sup>23</sup> in the history of physics, a conserved quantity of a field is found and then the  
<sup>24</sup> underlying symmetry of the field is inferred. Gauge symmetries are symmetries  
<sup>25</sup> among the internal degrees of freedom of the field (components of the tensor),  
<sup>26</sup> which give rise to quantities associated with fields. By specifying the symmetries  
<sup>27</sup> of a system the dynamics and conserved quantities of the system may be succinctly  
<sup>28</sup> defined.

### <sup>29</sup> 1.3 $U(1)_{EM}$ Local Gauge Invariance

<sup>30</sup> The Lagrangian of Quantum Electrodynamics (QED) describes the electro-  
<sup>31</sup> magnetic force. QED may be derived by requiring local  $U(1)_{EM}$  gauge invariance  
<sup>32</sup> of the free dirac fermion Lagrangian,  $\psi$ :

$$\mathcal{L} = i\bar{\psi}\gamma^\mu\partial_\mu\psi - m\bar{\psi}\psi \quad (1.1)$$

<sup>33</sup> This symmetry may be represented as a complex number with unit modulus,  
<sup>34</sup>  $e^{i\theta}$ .  $U(1)$  gauge invariance requires this gauge transformation of  $\psi$  will leave the  
<sup>35</sup> Lagrangian unchanged.

$$\psi(x) \rightarrow \psi'(x) = e^{i\theta(x)}\psi(x) \quad (1.2)$$

<sup>36</sup> NB: This transformation is a local gauge transformation as  $\theta$  depends on the  
<sup>37</sup> spacetime coordinate.

<sup>38</sup> By requiring this symmetry of the free Dirac fermion Lagrangian:

$$\mathcal{L} = i\bar{\psi}\gamma^\mu\partial_\mu\psi - m\bar{\psi}\psi \quad (1.3)$$

<sup>39</sup> The mass term is unaffected, but the kinetic term is modified due to  $\theta(x)$ .

$$\mathcal{L} \rightarrow \mathcal{L}' = i\bar{\psi}e^{-i\theta(x)}\gamma^\mu\partial_\mu\psi e^{i\theta(x)} - m\bar{\psi}e^{-i\theta(x)}\psi e^{i\theta(x)} \quad (1.4)$$

<sup>40</sup>

$$= i\bar{\psi}\gamma^\mu(\partial_\mu\psi + i\psi\partial_\mu\theta) - m\bar{\psi}\psi \quad (1.5)$$

<sup>41</sup> The  $\partial_\mu\theta$  terms breaks the gauge invariance of the Lagrangian. By introducing a  
<sup>42</sup> new field,  $A_\mu$  we can recover the gauge invariance of the derivative. Now redefining  
<sup>43</sup> the derivative as the covariant derivative:

$$D_\mu\psi \equiv (\partial_\mu - iqA_\mu)\psi \quad (1.6)$$

<sup>44</sup> And letting  $A_\mu$  transform under  $U(1)$  as:

$$A_\mu \rightarrow A_\mu + \delta A_\mu \quad (1.7)$$

<sup>45</sup> The transformed covariant derivative becomes:

$$D_\mu\psi \rightarrow D_\mu\psi' = (\partial_\mu - iqA_\mu)\psi' \quad (1.8)$$

<sup>46</sup>

$$= (\partial_\mu - iq(A_\mu + \delta A_\mu))\psi e^{i\theta} \quad (1.9)$$

<sup>47</sup>

$$= e^{i\theta}D_\mu + ie^{i\theta}\psi(\partial_\mu\theta - q\delta A_\mu) \quad (1.10)$$

<sup>48</sup> The covariant derivative can be made gauage invariant by setting the last term  
<sup>49</sup> to zero.

$$\delta A_\mu = \frac{1}{q} \partial_\mu \theta \quad (1.11)$$

50 So now  $A_\mu$  transforms as:

$$A_\mu \rightarrow A_\mu + \frac{1}{q} \partial_\mu \theta \quad (1.12)$$

51 Finally, replacing the derivative with the covariant derivative the Dirac La-  
52 grangian we have:

$$\mathcal{L} = i\bar{\psi}\gamma^\mu D_\mu \psi - m\bar{\psi}\psi - \frac{1}{4}F_{\mu\nu}F^{\mu\nu} \quad (1.13)$$

53

$$= \mathcal{L}_{QED} \quad (1.14)$$

54 Here  $F_{\mu\nu} \equiv \partial_\mu A_\nu - \partial_\nu A_\mu$ . This last term in the Lagrangian is the kinetic  
55 energy of the gauge boson field.

56 So we have derived the QED Lagrangian. By requiring the free Dirac La-  
57 grangian to be invariant under U(1) transformations we have generated a new  
58 gauge boson field,  $A_\mu$ , which describes the photon. As expected the photon inter-  
59 acts with fermions.

60 Stepping back, a global U(1) gauge symmetry of the free Dirac Lagrangian  
61 implies we cannot measure the absolute phase of a charged particle. A local U(1)  
62 gauge symmetry changes the phase of fields differently across space time. For this  
63 type of transformation to leave the Lagrangian invariant, we had to introduce an  
64 additional field,  $A_\mu$ , which "communicates" these phase changes across space-time.  
65 In less formal language this effectively means: if the field at one location changes,  
66 this change is conferred to other particles via  $A_\mu$ .

## 67 1.4 Yang-Mills Gauge Theories

68 Requiring  $U(1)_{EM}$  gauge invariance of the free Dirac Lagrangian gave us QED.

69 Requiring different gauge symmetries we can derive the structure of other inter-

70 actions. Any gauge symmetry may be written as:

$$\psi_i \rightarrow \exp(i\theta^a T_{ij}^a) \psi_j \quad (1.15)$$

71 Here  $\theta$  is a dimensionless real parameter and  $T$  is the generator of the gauge

72 symmetry group. With this the covariant derivative can be written as:

$$D_\mu \psi_i \equiv \partial_\mu \psi_i + ig A_\mu^a T_{ij}^a \psi_j \quad (1.16)$$

73 Then the gauge field must transform as:

$$A_\mu^a \rightarrow A_\mu^a - \frac{1}{g} \partial_\mu \theta^a - f^{abc} \theta^b A_\mu^c \quad (1.17)$$

74 Here  $f$  is the structure constant of the gauge group. The field strength tensor

75 is given by:

$$F_{\mu\nu}^a \equiv \partial_\mu A_\nu^a - \partial_\nu A_\mu^a - g f^{abc} A_\mu^b A_\nu^c \quad (1.18)$$

76

$$F_{\mu\nu}^a \rightarrow F_{\mu\nu}^a - f^{abc} \theta^b F_{\mu\nu}^c \quad (1.19)$$

77 This gives the Yang-Mills Lagrangian:

$$\mathcal{L}_{YM} = -\frac{1}{4} F_{\mu\nu}^a F_{\mu\nu}^a + i \bar{\psi}_i \gamma^\mu D_\mu \psi_i + m \bar{\psi}_i \psi_i \quad (1.20)$$

## 78 1.5 Particles in the Standard Model

79 The SM consists of fermions (half-integer spin matter constituents) and bosons  
80 (integer spin force mediators). Fermions are spinor representations of the Poincare  
81 group and can be further separated into leptons and quarks. Bosons are the result  
82 of requiring a particular symmetry among the spinor fields:

$$SU(3)_C \times SU(2)_L \times U(1)_Y \quad (1.21)$$

83  $SU(3)_C$  is the symmetry group of the strong force and generates eight gluon  
84 fields,  $G_\mu$ .  $SU(2)_L$  is the symmetry group of the Electroweak force and generates  
85 three electroweak boson fields, and  $U(1)_Y$  generates the photon field, where  $Y$  is  
86 the weak-hypercharge:

$$Y = 2(Q - T_3) \quad (1.22)$$

87  $Q$  is the electromagnetic charge, and  $T_3$  is the z-component of the weak isospin.  
88 Weak isospin is the charge associated with the  $SU(2)_L$  symmetry. The correspond-  
89 ing covariant derivative is then:

$$D_\mu \phi \equiv (\partial_\mu + ig_1 B_\mu Y_{L/R} + [ig_2 W_\mu^\alpha T^\alpha]_L + [ig_3 G_\mu^\alpha \tau^\alpha]_C) \psi \quad (1.23)$$

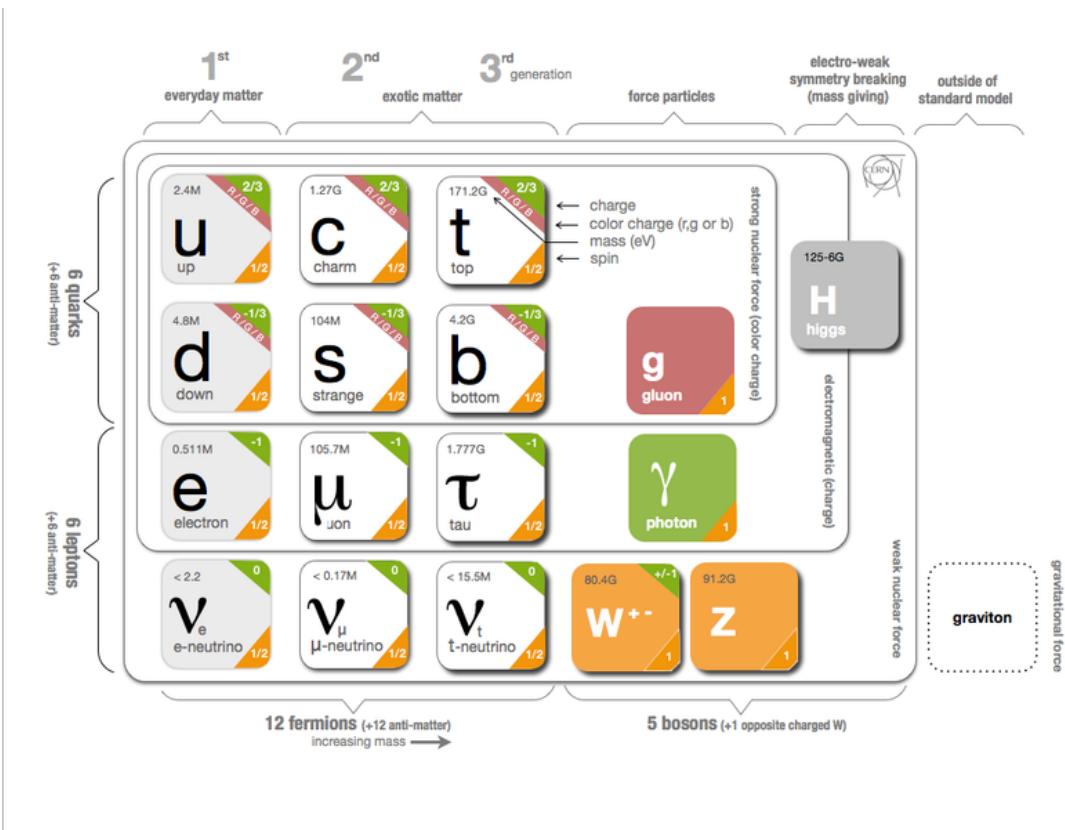

90 It is important to note that the gauge symmetry of the SM yields a particular  
91 structure of the fermion representations. So for a given fermion to interact with  
92 a given gauge field it must have a non-zero corresponding Noether charge for  
93 that gauge symmetry. If the corresponding Noether charge is zero, that fermion  
94 transforms as a singlet and does not participate in that gauge interaction.

95 Fermions are divided into quarks and leptons based on their transformations  
96 under  $SU(3)_C$ . Quarks transform as color triplets. Leptons transform as color

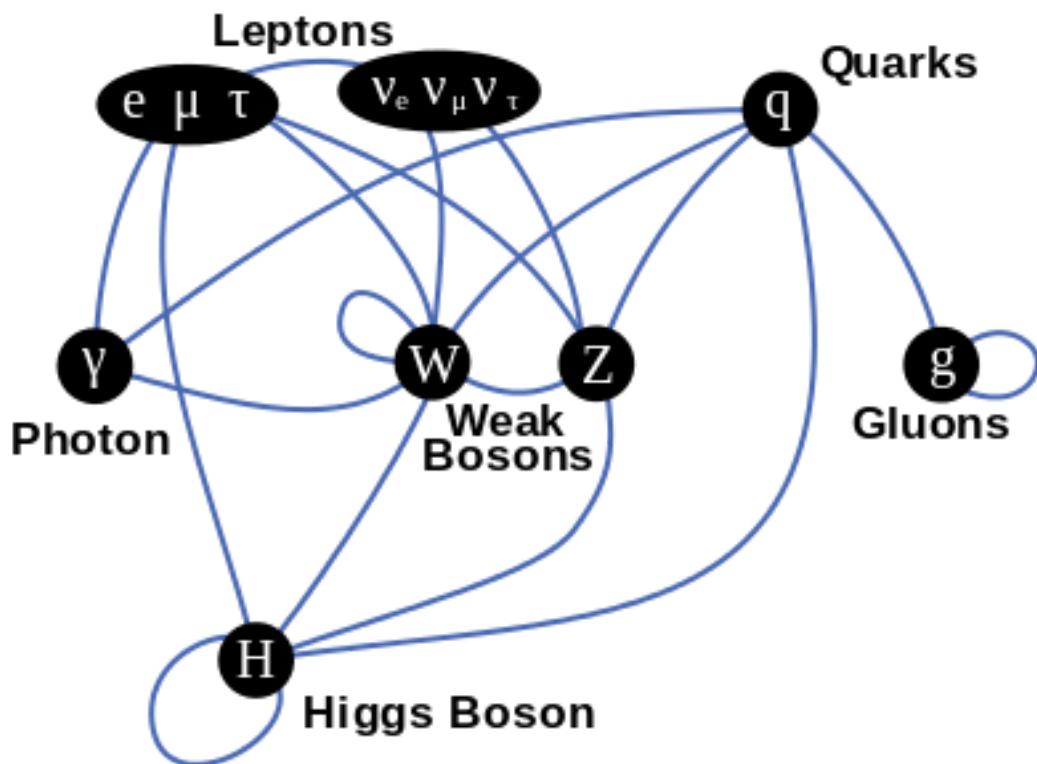

singlets and consequently do not interact with gluons. Fermions may be further  
 classified by their  $SU(2)_L$  interactions. Only the left-chiral part of fermions (denoted by L here) transform as  $SU(2)_L$  doublets, the right-chiral part forms singlets under this gauge. Lastly, all these groups of particles come in three generations, each a heavier copy of the previous, but with differing flavor quantum numbers.  
 This is summarized in Table 1.1 and shown in Figures 1.1 and 1.2.

SM Fermion Gauge Group	First Generation	Second Generation	Third Generation	$(SU(3)_C, SU(2)_L, U(1)_Y)$ Representations
Left-handed quarks	$\begin{pmatrix} u_L^r & u_L^g & u_L^b \\ d_L^r & d_L^g & d_L^b \end{pmatrix}$	$\begin{pmatrix} c_L^r & c_L^g & c_L^b \\ s_L^r & s_L^g & s_L^b \end{pmatrix}$	$\begin{pmatrix} t_L^r & t_L^g & t_L^b \\ b_L^r & b_L^g & b_L^b \end{pmatrix}$	$(3, 2, \frac{1}{6})$
Right-handed quarks	$(u_R^r, u_R^g, u_R^b)$ $(d_R^r, d_R^g, d_R^b)$	$(c_R^r, c_R^g, c_R^b)$ $(s_R^r, s_R^g, s_R^b)$	$(t_R^r, t_R^g, t_R^b)$ $(b_R^r, b_R^g, b_R^b)$	$(3, 1, \frac{2}{3})$ $(3, 1, -\frac{1}{3})$
Left-handed leptons	$\begin{pmatrix} \nu_e^L \\ e_L \end{pmatrix}$	$\begin{pmatrix} \mu_e^L \\ \mu_L \end{pmatrix}$	$\begin{pmatrix} \tau_e^L \\ \tau_L \end{pmatrix}$	$(1, 2, -\frac{1}{2})$
Right-handed leptons	$e_R$	$\mu_R$	$\tau_R$	$(1, 1, -1)$

**Table 1.1:** Representations of the SM fermions under  $SU(3)_C \times SU(2)_L \times U(1)_Y$  gauge symmetry group.  $SU(2)_L$  gauge transformations allow one to go between rows and  $SU(3)_C$  transformations allow one to go between columns in these fermion representations. [REWORD]

**Figure 1.1:** The particles of the Standard Model.

**Figure 1.2:** Summary of how Standard Model particles interact with other Standard Model particles.

<sup>103</sup> Now we can understand the SM Lagrangian density as a Yang-Mills theory  
<sup>104</sup> with the gauge group:  $SU(3)_C \times SU(2)_L \times U(1)_Y$  with an additional  $SU(2)$  complex  
<sup>105</sup> scalar Higgs field doublet that will be discussed later.

$$\begin{aligned} \mathcal{L}_{SM} = & \underbrace{-\frac{1}{4}B_{\mu\nu}B^{\mu\nu} - \frac{1}{4}W_{\mu\nu}^aW^{a\mu\nu} - \frac{1}{4}G_{\mu\nu}^\alpha G^{\alpha\mu\nu}}_{\text{Kinetic Energies and Self-Interactions of Gauge Bosons}} \\ & + \underbrace{\bar{L}_i \gamma^\mu (i\partial_\mu - \frac{1}{2}g_1 Y_{iL} B_\mu - \frac{1}{2}g_2 \sigma^a W_\mu^a) L_i}_{\text{Kinetic Energies and EW Interactions of Left-handed Fermions}} \\ & + \underbrace{\bar{R}_i \gamma^\mu (i\partial_\mu - \frac{1}{2}g_1 Y_{iR} B_\mu) R_i}_{\text{Kinetic Energies and EW Interactions of Right-Handed Fermions}} \\ & + \underbrace{\frac{ig_3}{2} \bar{Q}_j \gamma^\mu \lambda^\alpha G_\mu^\alpha Q_j}_{\text{Strong Interactions between Quarks and Gluons}} \\ & + \underbrace{\frac{1}{2} |(i\partial_\mu - \frac{1}{2}g_1 B_\mu - \frac{1}{2}g_2 \sigma^a W_\mu^a)\Phi|^2 - V(\Phi)}_{\text{Electroweak Boson Masses and Higgs Couplings}} \\ & - (\underbrace{y_{kl}^d \bar{L}_k \Phi R_l + y_{kl}^u \bar{R}_k \tilde{\Phi} L_l}_{\text{Fermion Mass terms and Higgs Couplings}} + h.c.) \end{aligned}$$

<sup>106</sup> Here several abstract spaces are being spanned:

- <sup>107</sup> – a spans the three  $SU(2)_L$  gauge fields with generators expanded in Pauli  
<sup>108</sup> matrices,  $T^\alpha = \frac{1}{2}\sigma^\alpha$
- <sup>109</sup> –  $\alpha$  spans the eight  $SU(3)_C$  gauge fields, with generators expanded in Gell-  
<sup>110</sup> Mann matrices,  $\tau^\alpha = \frac{1}{2}\lambda^\alpha$
- <sup>111</sup> – L/R represent left and right projections of Dirac fermion fields. The Strong  
<sup>112</sup> interaction is not chiral, so  $Q = L+R$

113 –  $\mu$  and  $\nu$  are four-vector indices

114 –  $i, j, k$  are summed over the three generations of SM particles.

## 115 1.6 Higgs Mechanism

116 The SM Lagrangian without the addition of a Higgs field does not allow for  
117 gauge boson and fermion mass terms:  $\frac{1}{2}m_A^2 A_\mu A_\mu$  and  $m(\bar{\psi}\psi)$ , as these terms are  
118 not gauge invariant. By introducing the Higgs field, mass terms for these particles  
119 may be included in a gauge invariant way. This field is a complex doublet with a  
120 potential  $V(\Phi)$ :

$$\Psi = \begin{pmatrix} \Phi^\dagger \\ \Phi^0 \end{pmatrix} \quad (1.24)$$

121  $V(\Phi) = \mu^2 \Phi^\dagger \Phi + \lambda |\Phi^\dagger \Phi|^2 \quad (1.25)$

122 The minima of this field occurs for  $|\Phi| = \sqrt{\frac{\mu^2}{2\lambda}} \equiv \frac{v}{2}$ . This yields degenerate  
123 minima, this symmetry is broken by choosing a specific minima (a.k.a. sponta-  
124 neous symmetry breaking). By convention  $\Phi_{min} = \frac{1}{\sqrt{2}} \begin{pmatrix} 0 \\ v \end{pmatrix}$  is chosen. This means  
125 the ground state of the Higgs field (Higgs vacuum) is non-zero,  $\sqrt{\frac{-\mu^2}{\lambda}}$ . The Higgs  
126 Field may now be expanded around this new ground state:

$$\Phi(x) = \frac{1}{\sqrt{2}} \begin{pmatrix} 0 \\ v + h(x) \end{pmatrix} \quad (1.26)$$

127 This non-zero Higgs vacuum now generates mass terms for the gauge bosons  
128 from the following term in the Lagrangian:

$$|(-\frac{1}{2}g_1B_\mu - \frac{1}{2}g_2\sigma^aW_\mu^a)\Phi|^2 = \frac{1}{2}m_W^2W_\mu^+W^{-\mu} + \frac{1}{2}m_Z^2Z_\mu Z^\mu \quad (1.27)$$

129 where:

$$W_\mu^\pm \equiv \frac{1}{\sqrt{2}}(W_\mu^1 \mp iW_\mu^2) \quad (1.28)$$

$$\begin{aligned} \text{130} \quad Z_\mu &\equiv \frac{1}{\sqrt{g_1^2 + g_2^2}}(g_2W_\mu^2 - g_1B_\mu) \end{aligned} \quad (1.29)$$

$$\begin{aligned} \text{131} \quad m_W &= \frac{vg_2}{\sqrt{2}} \end{aligned} \quad (1.30)$$

$$\begin{aligned} \text{132} \quad m_Z &= \frac{v}{\sqrt{2}}\sqrt{g_1^2 + g_2^2} \end{aligned} \quad (1.31)$$

133 The Higgs field also generates a mass term for the Higgs boson and self-  
134 interactions for the Higgs boson.

## 135 1.7 Electroweak Theory

136  $SU(2)_L$  generates  $W^\pm, W^0$  gauge bosons, which would be massless if  $SU(2)_L$   
137 was a perfect symmetry. These bosons are massive as this symmetry is broken.

138 The mass eigenstates,  $Z$  and  $\gamma$  given by:

$$\begin{pmatrix} Z_\mu \\ A_\mu \end{pmatrix} = \begin{pmatrix} \cos\theta_W & -\sin\theta_W \\ \sin\theta_W & \cos\theta_W \end{pmatrix} \begin{pmatrix} W_\mu^3 \\ B_\mu \end{pmatrix} \quad (1.32)$$

139 Here  $\theta_W$  is the Weinberg angle given by:

$$\cos\theta_W = \frac{g_2}{\sqrt{g_1^2 + g_2^2}} = \frac{m_W}{m_Z} \quad (1.33)$$

## <sup>140</sup> 1.8 Quantum ChromoDynamics

<sup>141</sup> As mentioned earlier the Strong Force, which binds the proton together, is  
<sup>142</sup> mediated by gluons. Quantum Chromodynamics is the QFT which describes the  
<sup>143</sup> interactions of quarks and gluons via  $SU(3)_C$  symmetry. QCD contains features  
<sup>144</sup> not present in Electroweak Interactions due to  $SU(3)_C$  generators not commuting  
<sup>145</sup> (a.k.a.  $SU(3)_C$  is a non-abelian group). For example, in QCD there is color  
<sup>146</sup> confinement and asymptotic freedom due to the structure constants being non-  
<sup>147</sup> zero. Requiring  $SU(3)_C$  local gauge invariance implies:

$$\psi(x) \rightarrow \psi(x)' = \exp[i g_S \alpha(x) \cdot \hat{T}] \psi(x) \quad (1.34)$$

<sup>148</sup> where  $\alpha(x)$  is the local phase function,  $g_S$  is the strong coupling constant, and  
<sup>149</sup>  $\hat{T}$  are the eight generators of  $SU(3)$  (note  $\hat{T}^a = \frac{1}{2}\lambda^a a$ , where  $\lambda^a$  are the Gell-Mann  
<sup>150</sup> matrices). As the Gell-Mann matrices are 3x3, this means  $\psi$  has three degrees of  
<sup>151</sup> freedom under these  $SU(3)$  rotations. So we represent  $\psi$  under  $SU(3)$  rotations  
<sup>152</sup> as:

$$\psi = \begin{pmatrix} \psi_{red} \\ \psi_{green} \\ \psi_{blue} \end{pmatrix} \quad (1.35)$$

<sup>153</sup> Consequently, particle fields transforming under  $SU(3)$  rotations have three  
<sup>154</sup> components which physicists describe as color components (red, green, and blue).  
<sup>155</sup> A particle's corresponding antiparticle has the corresponding anticolor. This color  
<sup>156</sup> is the "charge" of QCD and is conserved under  $SU(3)$  rotations. Combining colors,  
<sup>157</sup> color neutral states (e.g. red and antired, or red, green and blue) may be created.  
<sup>158</sup> For the Free Dirac Lagrangian to remain invariant under  $SU(3)$  transformations,  
<sup>159</sup> we must again postulate a boson field that modifies the derivative. The gluon

<sub>160</sub> field tensor is given by ( $\alpha = 1, \dots, 8$ ):

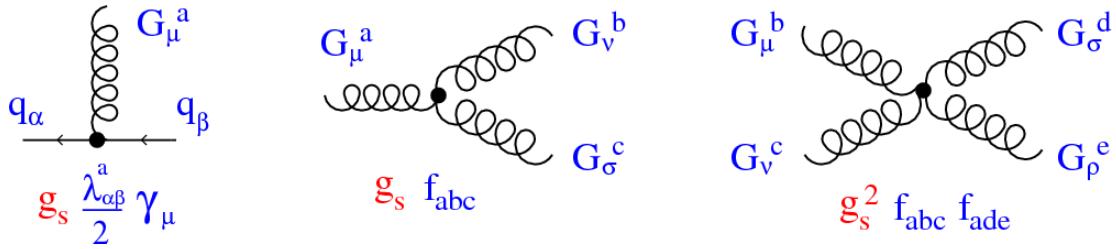

$$G_{\mu\nu}^k = \partial^\mu G_\alpha^\nu - \partial^\nu G_\alpha^\mu - g_S f^{\alpha\beta\gamma} G_\beta^\mu G_\gamma^\nu \quad (1.36)$$

<sub>161</sub> Here  $f^{\alpha\beta\gamma}$  are the structure constants of  $SU(3)$ . Combining all this gives the  
<sub>162</sub> QCD Lagrangian:

$$\mathcal{L}_{QCD} = \bar{\psi}_q i\gamma^\mu (D_\mu)_{ij} \psi^{qj} - m \bar{\psi}^{qi} \psi_{qi} - \frac{1}{4} G_{\mu\nu}^\alpha G^{\alpha\mu\nu} \quad (1.37)$$

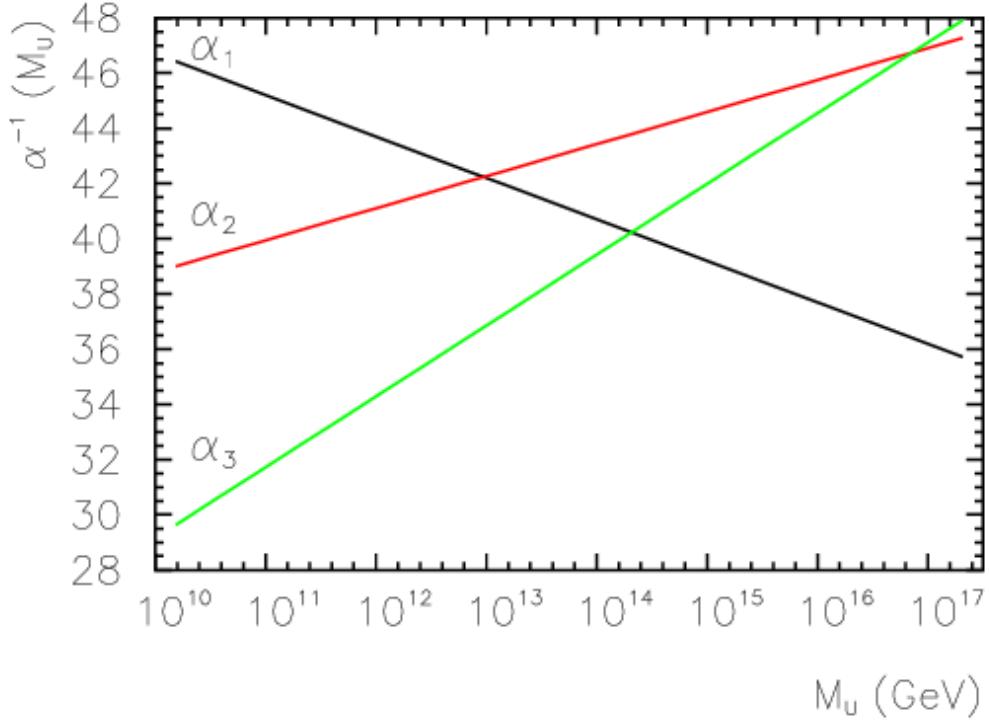

<sub>163</sub> Here  $i$  are the color indices, and  $q$  are the quark flavors. It is important to  
<sub>164</sub> note that quarks transform under the fundamental representation of  $SU(3)$ , while  
<sub>165</sub> gluons transform under the adjoint representation. This means quarks carry a  
<sub>166</sub> single color charge (red, green, blue, antired, antigreen, antiblue) and gluons carry  
<sub>167</sub> a color and anticolor charge.

<sub>168</sub> Figure 1.3 shows the three dominant QCD interactions. Since gluons carry  
<sub>169</sub> color charge, they interact with one another. This does not occur in QED, as  
<sub>170</sub> photons do not have electric charge and therefore do not interact with each other.  
<sub>171</sub> In QED, a bare electron's effective charge is largest closest to the electron and  
<sub>172</sub> decreases as a function of distance. This is because the QED vacuum fills with  
<sub>173</sub> particle antiparticle pairs spontaneously, which screen the charge of the bare elec-  
<sub>174</sub> tron. The larger the distance from the electron, the smaller the effective charge  
<sub>175</sub> and therefore the weaker the force. So for a pair of electrons, as the distance  
<sub>176</sub> between them increases the repulsive force decreases and they may be observed  
<sub>177</sub> separately.

**Figure 1.3:** This figure shows the three dominant QCD interactions. From Ref. [14]

178        As the distance from a quark increases it's effective color charge increases due  
 179        to the vacuum polarization in QCD. Color charge grows as the distance from  
 180        the source increases (a.k.a. color is anti-screened in QCD). In this way, strong  
 181        interactions become stronger at large distances (low momenta interactions). At  
 182        small distances (large momenta interactions) strong interactions are significantly  
 183        weaker and considered nearly free. This effect of referred to as asymptotic freedom.  
 184        At large distances, a quark's effective charge is large and the strong force is more  
 185        significant. This force becomes so strong that quarks form colorless bound states  
 186        instead of remaining free particles. This effect is known as color confinement.  
 187        This running of all SM fields is shown in Figure 1.4.

**Figure 1.4:** Strength of the U(1), SU(2), and SU(3) gauge couplings as a function of the energy scale of the interaction ( $Q$ ). From Ref. [10]

Commonly the change in a particle's effective charge under a given force is quantified with  $\beta(r) \equiv -\frac{de(r)}{d\ln r}$ , where  $e(r)$  is the effective charge of a given particle under a force. In QED this function is positive but in QCD this function is negative leading to confinement and asymptotic freedom. Moreover, one can calculate how the coupling ( $\alpha$ ) of a force varies with energies. (More deeply this amounts to incorporating renormalization and vacuum polarization in the boson propagators).

For QCD this is:

$$\alpha_S(x) = \frac{\alpha_S(\mu^2)}{1 + \beta_0 \alpha_S(\mu^2) \ln(Q^2/\mu^2)} \quad (1.38)$$

195

$$\beta_0 = \frac{11N_c - 2n_f}{12\pi} \quad (1.39)$$

196 where  $Q$  is the momentum of the force is probed at,  $\mu^2$  is the renormalization scale.

198 As stated previously, quarks and gluons have not been observed in isolation.  
199 Instead they form bound colorless states. Hadronization is the process by which  
200 quarks and gluons form hadrons. The process of hadronization is still an active  
201 area of research. One qualitative description is shown in Figure BLAH. In this  
202 figure, as two quarks separate the color field between them is restricted to a tube  
203 with energy density of  $\sim 1$  GeV/fm. As they separate further, the energy in the  
204 color field increases, until there is enough energy to produce  $q\bar{q}$  pairs, which breaks  
205 the color field. This process repeats until quarks and antiquarks have low enough  
206 energy to form colorless hadrons. The resulting spray of hadrons is called a jet.

207 Since quarks and gluons carry different color charges, their respective jets have  
208 different properties. As quarks carry only a single color charge (vs. gluons which  
209 have color and anticolor charge), so their jets have less constituent particles. More  
210 precisely, the Altarelli-Parisi splitting functions [3] contain a factor  $C_A$  for gluon  
211 radiation off a gluon and  $C_F$  for gluon radiation off a quark ( $C_A/C_F = 9/4$ ). These  
212 color factors are the prefactor in the Feynman diagrams for these processes [1],  
213 which leads to gluon jets having more constituents and therefore more tracks than  
214 quark jets. Gluon jets also tend to have a larger radius with lower momentum  
215 constituents than quarks. There are many novel techniques to distinguish quarks  
216 from gluons. For this study the number of charged particles will be focused on.

<sub>217</sub> **Chapter 2**

<sub>218</sub> **Standard Model Successes and**

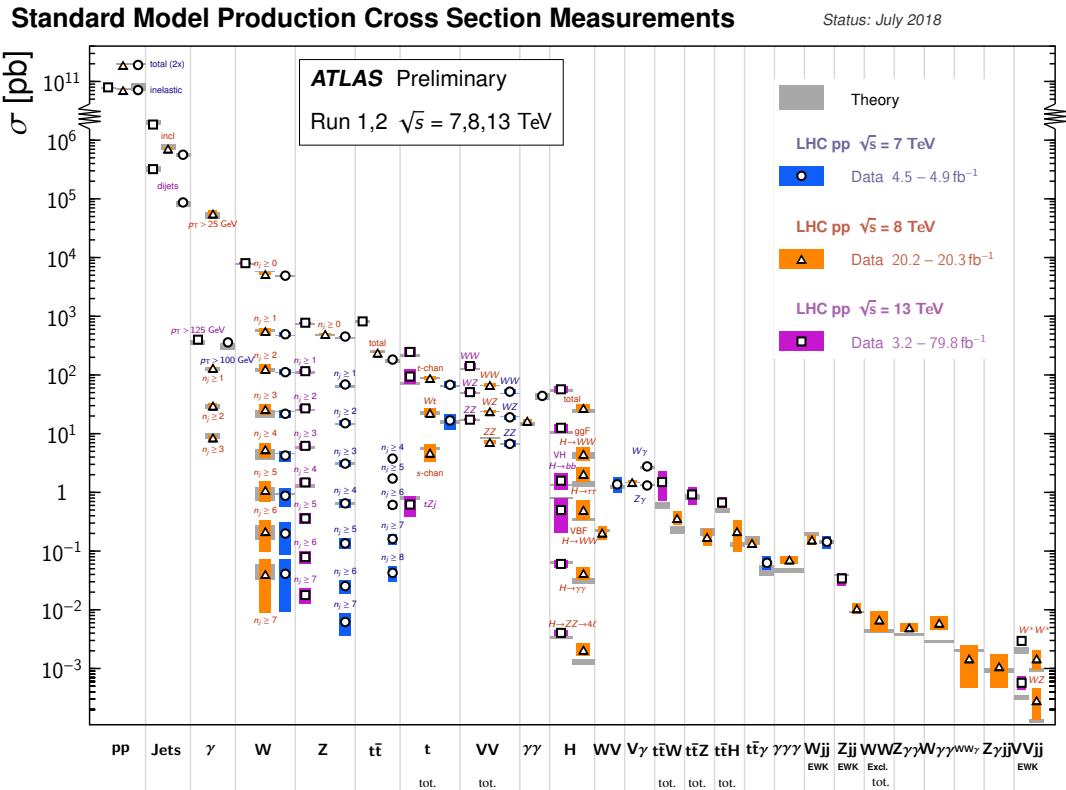

<sub>219</sub> **Limitations**

<sub>220</sub> The Standard Model has consistently described much of reality to an extreme  
<sub>221</sub> degree of accuracy. It has predicted cross sections for strong and electroweak  
<sub>222</sub> processes that span over ten order of magnitude correctly [see Fig 2.1] and contains  
<sub>223</sub> no known logical inconsistencies. Despite the strength and reality of the Standard  
<sub>224</sub> Model, it still fails to describe aspects of reality and suffers from aesthetic issues.  
<sub>225</sub> To date, dark matter and energy comprise  $\sim 95\%$  of the universe, but are not  
<sub>226</sub> accounted for in the SM. Additionally, neutrinos are known to have mass but are  
<sub>227</sub> massless in the SM. There are mechanisms for introducing massive neutrinos in  
<sub>228</sub> the SM, but these mechanisms create hierarchy problems.

<sub>229</sub> Possibly the most significant aesthetic issue is the hierarchy between the elec-  
<sub>230</sub> troweak and Planck scales. The electroweak scale is the scale of electroweak  
<sub>231</sub> symmetry breaking. The Planck scale is the scale where the gravitational force  
<sub>232</sub> is comparable in strength to the other forces. (This is also the scale where the  
<sub>233</sub> gravitational potential energy of two objects separated by a distance  $r$  is equal to  
<sub>234</sub> the energy of a photon with a wavelength  $r$ .) The Planck scale is where the SM

235 breaks down, as there is not an experimentally verified theory of quantum gravity,  
236 and at this scale gravity cannot be ignored (like it can at the electro-weak scale).  
237 These scales differ by  $\sim 30$  orders of magnitude. Understanding the difference  
238 in these energy scales, may help explain the weakness of gravity at electroweak  
239 scales, and possibly a QFT for gravity. (NB: This hierarchy can also be framed in  
240 terms of the corrections to the Higgs mass, which depend on the UV cutoff scale -  
241 where the SM is suppose to break, which is taken at the Planck scale. This leads  
242 the quantum corrections to the Higgs mass to force the Higgs mass to  $\sim 10^{18}$   
243 TeV.)

244 These stark contrasts in scales may indicate that a more fundamental theory  
245 exists. It is hoped that such a theory would explain and motivate some of the ad-  
246 hoc features of the SM. In particular, there currently are no experimentally verified  
247 explanations of why there are three generations of fermions, the values of the 19  
248 SM parameters (6 quark masses, 3 charged lepton masses, 3 gauge couplings,  
249 Higgs parameters ( $\mu^2, \lambda$ )), the structure of the fermion representations, etc.

**Figure 2.1:** A comparison of cross section measurements at  $\sqrt{s} = 7,8,13$  TeV from ATLAS compared to theoretical measurements. From Ref. [5]

250 **Chapter 3**

251 **New Physics Models with  
252 Diboson Resonances**

253 **3.1 Randall Sundrum Bulk Model**

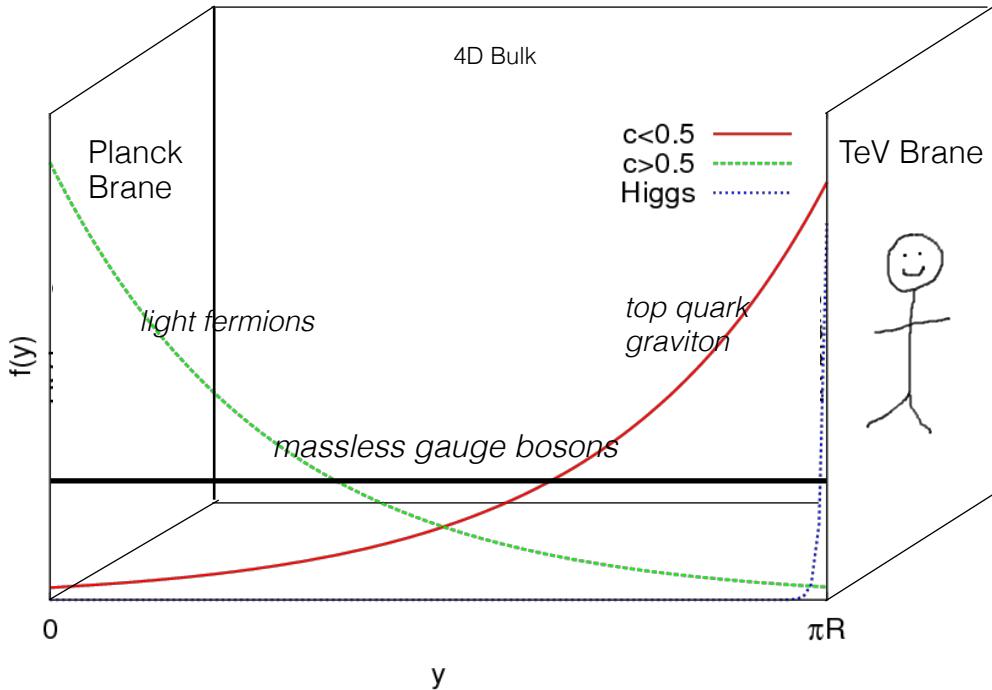

254 The electroweak-planck hierarchy may be explained by the existence of extra  
255 dimensions, like the 5D Randall Sundrum Bulk Model ([15], [2]). In this model,  
256 there is one extra warped spatial dimension,  $y$ , with a metric:

$$ds^2 = e^{-2k|y|} \eta_{\mu\nu} dx^\mu dx^\nu + dy^2 \quad (3.1)$$

257 where  $e^{-k|y|}$  is the warp factor of the extra dimension, which is compactified on  
258 a  $S^1/Z_2$  orbifold (a.k.a. a circle where  $y \rightarrow -y$ ). This can be visualized as every  
259 point in space time having a line extending from it a distance  $L$ , representing  
260 this fifth dimension. At the end of this line is the Planck brane. This fourth  
261 spatial dimension separates two 4-D branes: Planck brane and TeV brane. We  
262 live on the TeV brane, as shown in Figure 3.1. The Higgs field (and to a lesser  
263 degree the top quark and graviton fields) is localized near the TeV Brane, while

264 the light fermion fields are localized more near the Planck brane. Fundamental  
 265 parameters are set on the Planck brane. The warp factor may be scaled away from  
 266 all dimensionless SM terms by field redefinitions. However, the only dimensionful  
 267 parameter,  $m_H^2 = v^2$  is rescaled by  $\tilde{v} \sim e^{-kL} M_{Pl} \sim 1\text{TeV}$  for  $kL \sim 35$ , explaining  
 268 why gravity is so weak on the TeV brane. Also, by localizing the light fermion  
 269 fields near the Planck brane and top and graviton fields near the TeV brane, the  
 270 light quarks will have smaller masses.

271 The two free parameters of this theory are  $M_{Pl}$  and  $k$ . Based on this RS Bulk  
 272 model, all SM particles should have Kaluza-Klein (KK) excitations. In particular,  
 273 the graviton would have KK excitations that prefer to decay to WW or ZZ, which  
 274 is why this analysis searches for RS Gravitons.

**Figure 3.1:** Cartoon of RS Bulk Model

<sup>275</sup> **3.2 Extended Scalar Sector**

<sup>276</sup> A further striking asymmetry of the SM is the simplicity of the scalar sector in  
<sup>277</sup> comparison to the boson and fermion sectors. To date, the scalar sector has only  
<sup>278</sup> one member, the Higgs boson. Therefore, it is natural to posit an extension to the  
<sup>279</sup> scalar sector. From a theoretical standpoint this could also help generate baryon  
<sup>280</sup> asymmetry through additional sources of CP violation. This analysis searches for  
<sup>281</sup> a simple extension to the scalar sector as proposed in Ref. [16]. The extended  
<sup>282</sup> scalar sector includes a real Higgs singlet ( $S$ ) and complex  $SU(2)_L$  doublet ( $\Phi$ )  
<sup>283</sup> (the SM Higgs), where mass eigenstates are mixtures of the fields.  $S$  has a vev of  
<sup>284</sup>  $v$  and  $\Phi$  has a vev of  $x$ . This then gives a Lagrangian of:

$$\mathcal{L} \supset (D^\mu \Phi)^\dagger D_\mu \Phi + \partial^\mu S \partial_\mu S - m^2 \Phi^\dagger \Phi - \mu^2 S^2 + \lambda_1 (\Phi^\dagger \Phi)^2 + \lambda_2 S^4 + \lambda_3 \Phi^\dagger \Phi S^2 \quad (3.2)$$

<sup>285</sup> The mass eigenstates of the scalar sector are then mixtures of  $S$  and  $\Phi$  and  
<sup>286</sup> the free parameters of the theory are  $m_H$ ,  $\sin \alpha$ , and  $\tan \beta = v/x$ . The fields are  
<sup>287</sup> then given by:

$$\Phi \equiv \begin{pmatrix} 0 \\ \frac{\tilde{h}+v}{\sqrt{2}} \end{pmatrix} \quad (3.3)$$

$$S \equiv \frac{h' + x}{\sqrt{2}} \quad (3.4)$$

<sup>288</sup> Diagonalizing the mass matrix leads to the mass eigenstates  $h$  (discovered  
<sup>289</sup> Higgs boson) and  $H$  (the physical particles):

$$\begin{pmatrix} h \\ H \end{pmatrix} = \begin{pmatrix} \cos \alpha & -\sin \alpha \\ \sin \alpha & \cos \alpha \end{pmatrix} \quad (3.5)$$

291 This suppressed h and H production and SM H couplings:

$$BR_{H \rightarrow SM} = \sin^2 \alpha \times \frac{\Gamma_{SM, H \rightarrow SM}}{\Gamma_{tot}} \quad (3.6)$$

292 Moreover, in the case that  $m_H > m_h$ ,  $H \rightarrow hh$  is possible. This further suppresses  
293  $H \rightarrow VV/ff$ . This search is most sensitive to  $H \rightarrow WW$ .

### 294 3.3 Simple Standard Model Extensions

295 The RS Bulk model is motivated by resolving the hierarchy problem. Ex-  
296 tending the Scalar sector is a natural space to look for new physics due to the  
297 complexity of fermion and boson groups. There are many other interesting and  
298 well motivated frameworks, but there is a lack of completely predictive models,  
299 due to model flexibility (free parameters). Therefore it is hard for experimentalists  
300 to know which theories to search for in data. However, as seen in [13], a "Simpli-  
301 fied Model" approach may be taken. In the search for reasonably narrow width  
302 particles, as in this search, the search is not sensitive to all the details and free  
303 parameters of the theory. Generally such searches are only sensitive to the reso-  
304 nance mass and its interactions. Therefore, a theory's Lagrangian may be reduced  
305 to only retain this information (mass parameters and couplings). Experimental  
306 results using this framework may then be reinterpreted in a given theory.

307 In the simplified approach, the new resonance searched for is represented as  
308 a real vector field in the adjoint representation of  $SU(2)_L$  with vanishing hyper-  
309 charge. This results in one neutral and two charged bosons. Defined as:

$$V^\pm = \frac{V_\mu^1 \mp iV_\mu^2}{\sqrt{2}} \quad (3.7)$$

310  $V_\mu^0 = V_\mu^3 \quad (3.8)$

311      The SM Lagrangian is then augmented with the additional terms:

$$\mathcal{L} \supset -\frac{1}{4}D_{[\mu}V_{\nu]}^a D^{[\mu}V^{\nu]}{}^a + \frac{m_V^2}{2}V_\mu^a V^{a\mu} + ig_V c_H V_\mu^a H^\dagger \tau^a \overset{\leftrightarrow}{D}{}^\mu H + \frac{g^2}{g_V} c_F V_\mu^a J_F^{\mu a} \quad (3.9)$$

312      In order the terms represent: the kinetic,  $V$  mass, Higgs- $V$  interaction, and  
313       $V$ -left-handed fermion interaction terms. Phenomenologically the three physical  
314      particles this predicts are degenerate, where  $V$  couples most strongly to  $VV$ , via  
315      the  $g_V$  coupling factor. The dominant production modes are DY and VBF.

316      Two versions of HVT are considered, Model A and B. Model A is a weakly  
317      coupled model where  $g_V \sim 1$ , like the extended gauge symmetry discussed in Ref .  
318      [16]. Model B is a strongly coupled model, where  $1 < g_V < 4\pi$ . The width of the  
319      resonance grows with  $g_V$  so for this narrow resonance search only  $g_V$  is chosen to  
320      be less than 6 (so  $\Gamma/M < 10\%$ ). More precisely, the coupling of these resonances  
321      to fermions scales as  $g_f = g^2 c_F/g_V$ , where  $g$  is the SM  $SU(2)_L$  gauage coupling  
322      and  $c_F$  is the free parameter (expected to be of order 1 for Model A and B). This  
323      then means that for Model B the coupling is to fermions is more suppressed than  
324      for Model A, leading to a smaller DY production rate and BR to fermionic final  
325      states. The coupling of  $V$  to SM bosons scales as  $g_H = g_V c_H$ , where  $c_H$  is a  
326      free parameter on the order of 1 for Model A and B. So for small values of  $g_V$   
327      (i.e. Model A - weakly coupled theories) the BR to gauge bosons is smaller than  
328      for Model B. So weakly coupled vectors have large production cross sections and  
329      decay prominantly to leptons or jets, while strongly coupled vectors are produced  
330      less and decay predominantly to gauge bosons.

331      Vectors in Model A and B are generally produced via quark-anti-quark annihi-  
332      lation. The more rare production via vector-boson-fusion is considered by setting  
333       $g_H = 1$  and  $g_F = 0$ . In Model B diboson final states are enhanced as stated  
334      previously due to  $g_H$  and moreover the BR to  $WZ$ ,  $WH$ ,  $WW$ , and  $ZH$  are the

<sup>335</sup> same.

<sup>336</sup> In summary,  $V$  couples most strongly to left-handed fermions and  $VV$  dependent on  $g_V$ .

338

## Part II

339

## Experimental Setup

<sup>340</sup> **Chapter 4**

<sup>341</sup> **LHC**

<sup>342</sup> The Large Hadron Collider (LHC) is the highest-energy particle collider in the  
<sup>343</sup> world. It was designed to expand the frontier of high energy particle collisions in  
<sup>344</sup> energy and luminosity. This enables LHC experiments to test the Standard Model  
<sup>345</sup> and search for new physics at higher energies than tested with previous colliders.  
<sup>346</sup> Collisions at higher energies not only produce more massive particles but also  
<sup>347</sup> more weakly interacting particles. Fig. 4.1 shows production cross sections for  
<sup>348</sup> various processes at hadron colliders. The rate for electroweak physics pcoesses  
<sup>349</sup> including  $W$  and  $Z$  scale with the center-of-momentum energy,  $\sqrt{s}$ .

<sup>350</sup> The LHC consists of a 26.7 km (17 miles) ring, approximately 100 m un-  
<sup>351</sup> derground, outside Geneva, Switzerland. Counter-circulating proton (and occa-  
<sup>352</sup> sionally heavy ions) beams collide inside four experiments along the beam line:  
<sup>353</sup> ATLAS, CMS, LHCb, ALICE. ATLAS and CMS are general purpose detectors  
<sup>354</sup> designed to explore high energy frontier. LHCb is designed to study the physics  
<sup>355</sup> of  $b$ -quarks. ALICE specializes in studying heavy ion collisions.

## proton - (anti)proton cross sections

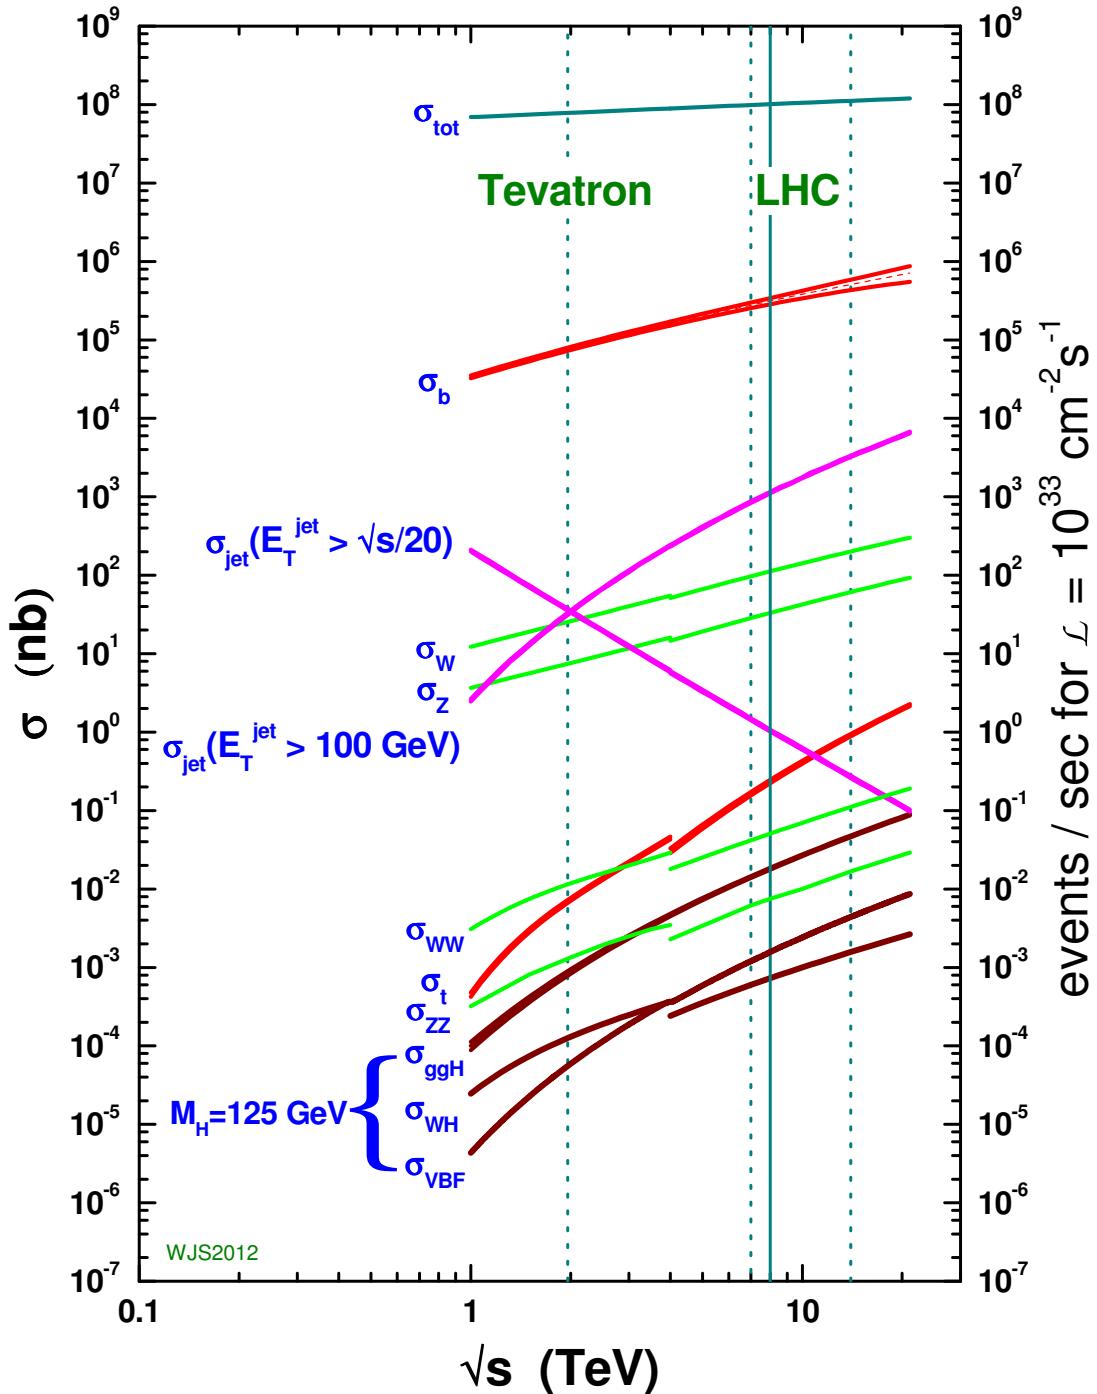

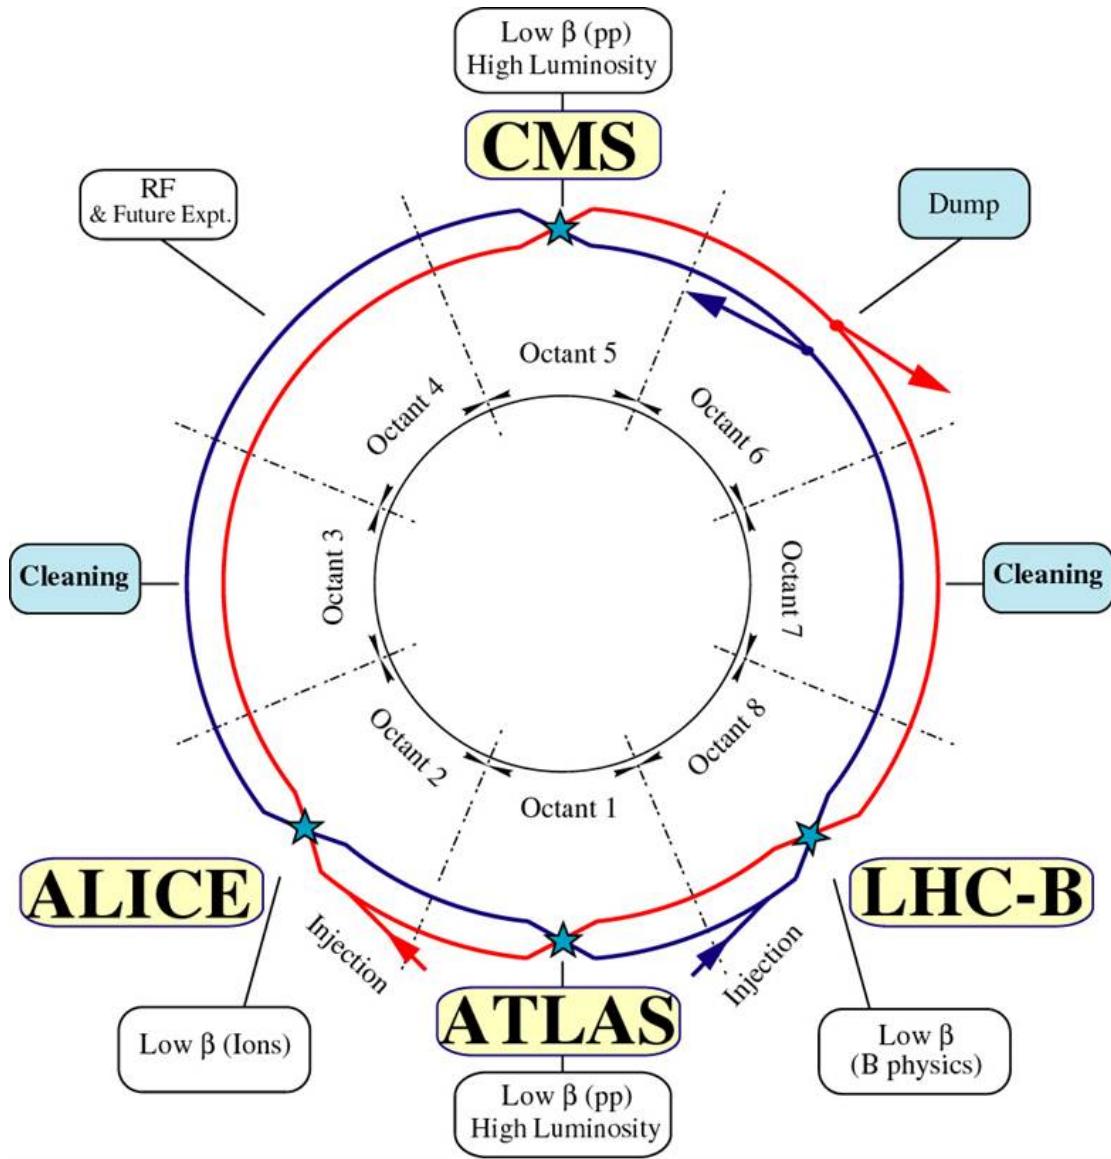

Figure 4.1: Scaling of cross sections with  $\sqrt{s}$ . Natasha: write more here

356      The first proton beams circulated in September, 2008. Nine days later an elec-  
357 trical fault lead to mechanical damage and liquid helium leaks in the collider. This  
358 incident delayed further operation until November 2009, when the LHC became  
359 the world's highest energy particle collider, at 1.18TeV per beam. This first oper-  
360 ational run continued until 2013, reaching 7 and 8 TeV collision energies. During  
361 this run a particle with properties consistent with the Standard Model Higgs bo-  
362 son was discovered. The next run began after a two year shutdown after upgrades  
363 to the LHC and experiments. This run lasted from 2013 to 2018 reaching 13 TeV  
364 collision energies. This analysis uses data from the second operational run.

## 365 **4.1 LHC Layout and Design**

366      The layout of the LHC is shown in Figure 4.2. The red and blue lines in the  
367 figure represent the counter-circulating proton beams. The LHC is divided into  
368 eight octants. Octant 4 contains the RF cavities that accelerate the protons and  
369 octant 6 contains the beam dump system. Octants 3 and 7 house the collimation  
370 systems for beam cleaning. The beams collide inside the four aforementioned  
371 experiments. Each octant contains a curved and straight section. The LHC  
372 magnets are built with NbTi superconductors cooled with super-fluid Helium to  
373 2K, creating a 8.3T magnetic field to bend the proton beams.

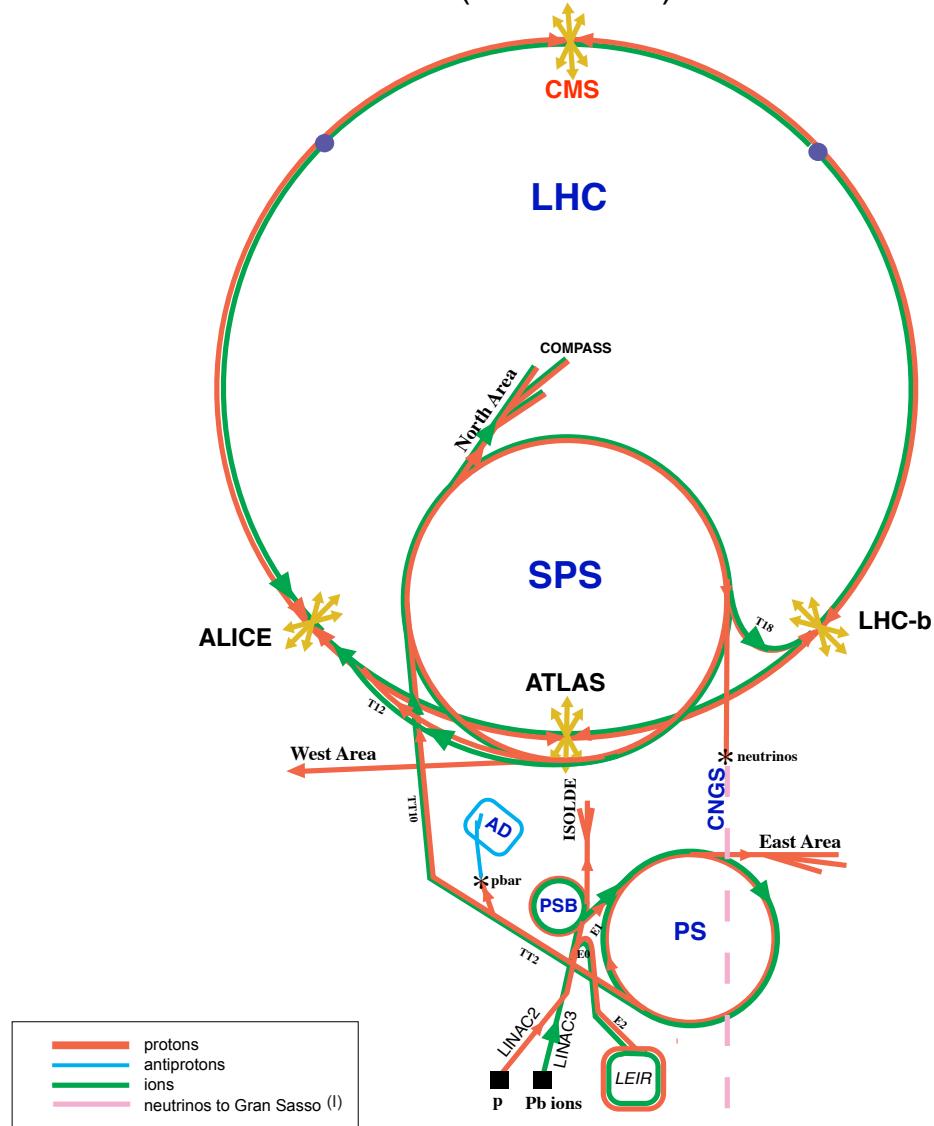

**Figure 4.2:** LHC Layout. Natasha write more

374        Four sequential particle accelerators are used to accelerate proton from rest  
 375        as shown in Figure 4.3. First, Hydrogen gas is ionized to produce protons which  
 376        are then accelerated to 50 MeV using Linac 2, a linear accelerator. The result-  
 377        ing proton beam is then passed to three circular particle accelerators: Proton  
 378        Synchrotron Booster, Proton Synchrotron, and Super Proton Synchrotron (SPS),

<sup>379</sup> accelerating protons to 1.4, 25, and 450 GeV, respectively. Once the protons exit  
<sup>380</sup> SPS, they are injected into the LHC at octant 2 and 8. Each proton bunch contains  
<sup>381</sup>  $\sim 10^{11}$  protons. The spacing between bunches is 25 ns, which means each beam  
<sup>382</sup> contains 3564 bunches. However, some bunches are left empty due to injection  
<sup>383</sup> and safety requirements, yielding 2808 bunches per beam. Once the proton beams  
<sup>384</sup> are injected they are accelerated to 13 TeV.

D. Manglunki, PS Div. CERN, 23.05.01

Figure 4.3: LHC Accelerator. Natasha write more

385 As many new physics models predict cross-sections below the weak scale it was  
386 important to design the LHC to be capable of collecting enough data, by running  
387 in high luminosity conditions. The machine luminosity depends only on beam  
388 parameters:

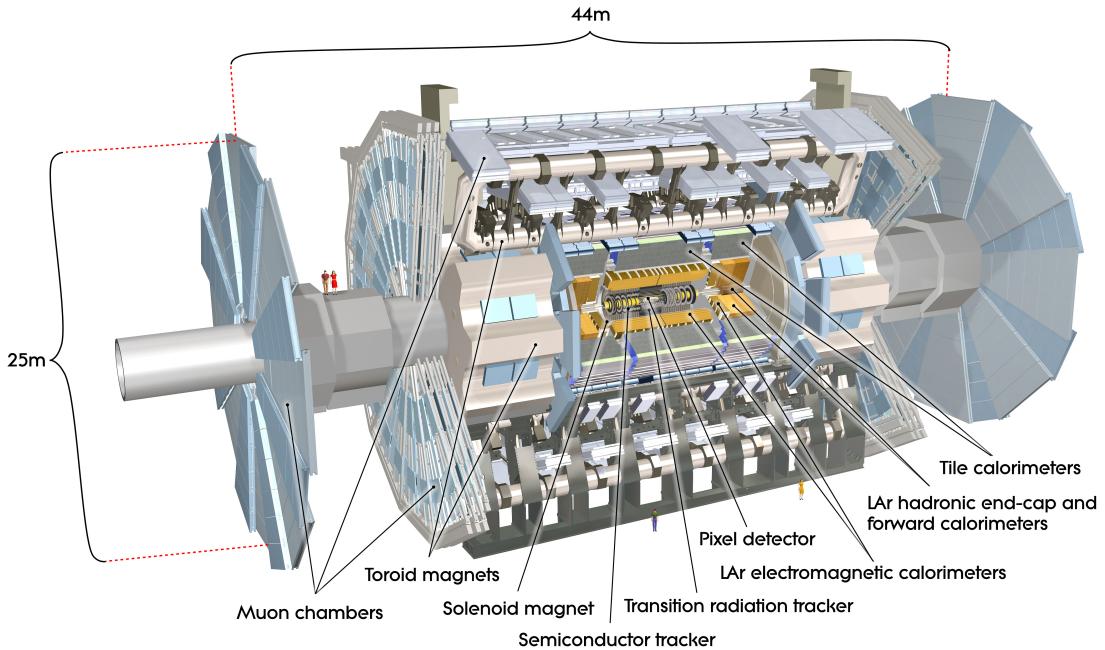

$$L = \frac{N_p^2 f}{4\epsilon\beta^*} F \quad (4.1)$$

389 where  $N_p$  is the number of protons per bunch,  $f$  is the bunch crossing frequency,  
390  $\epsilon$  is the transverse beam emittance,  $\beta^*$  is the amplitude function at the collision  
391 point, and  $F$  is the geometric luminosity reduction factor due to the beams crossing  
392 at an angle (rather than head-on).

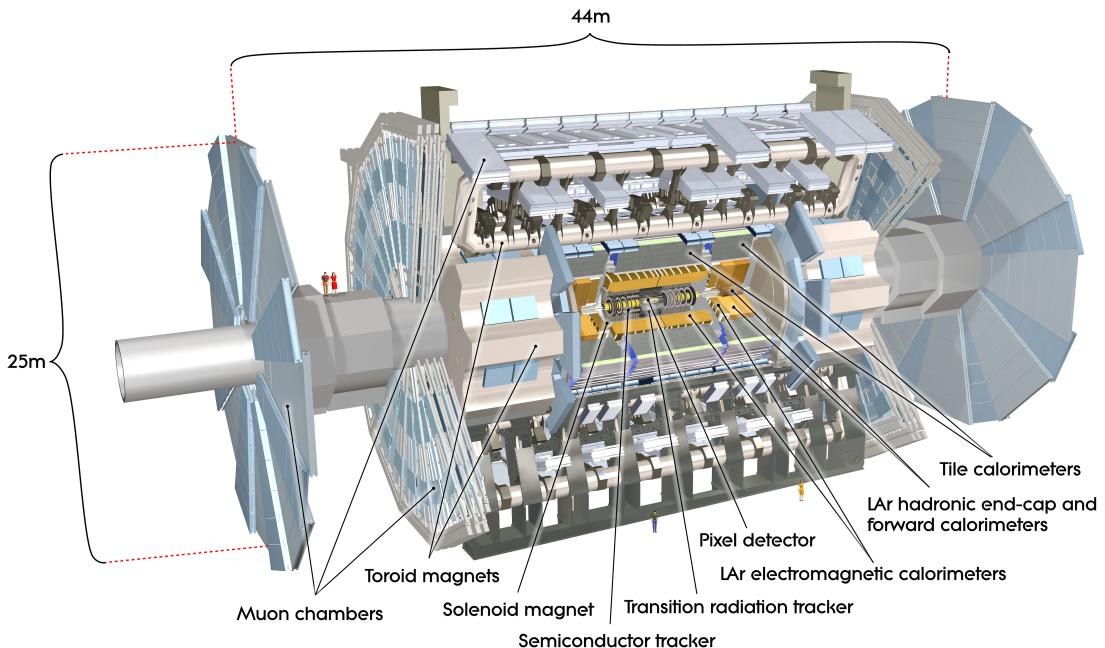

<sup>393</sup> **Chapter 5**

<sup>394</sup> **The ATLAS Detector**

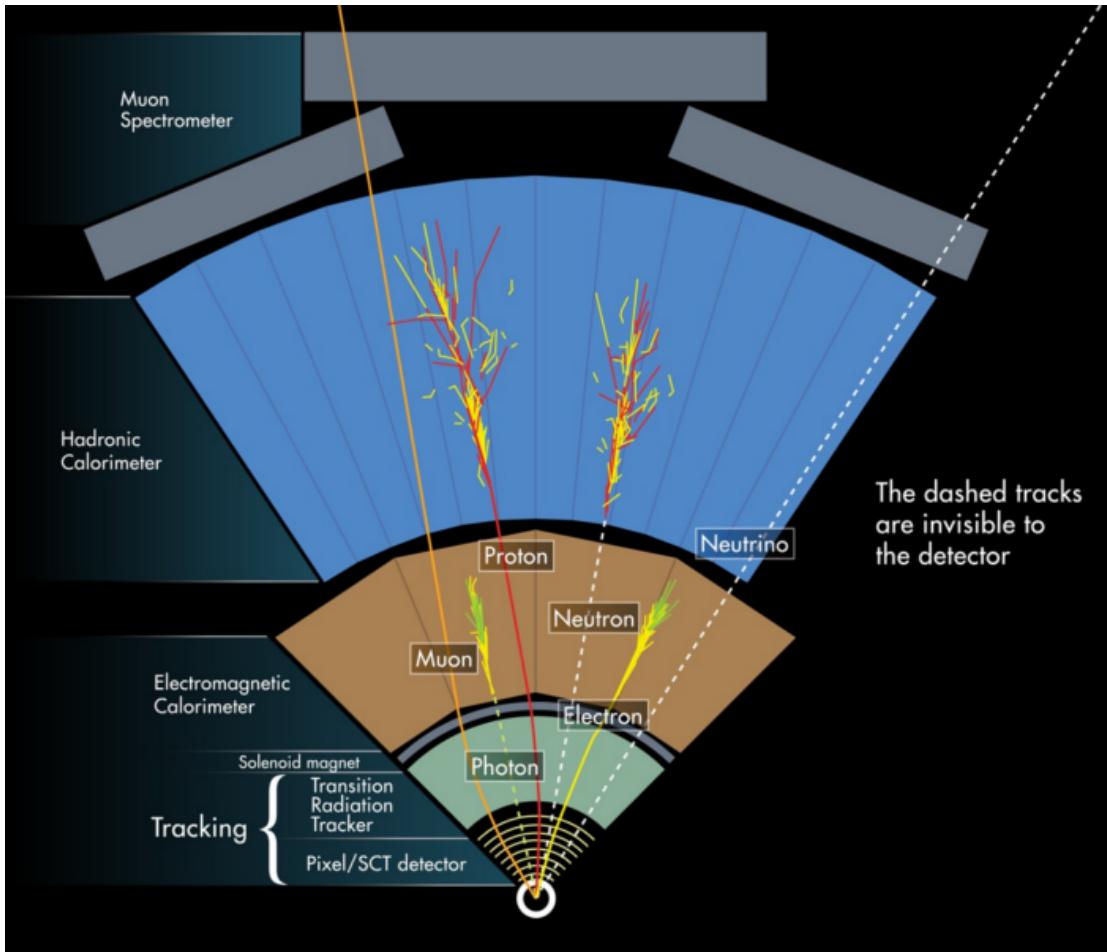

<sup>395</sup> The ATLAS detector measures the position, momentum and energy of parti-  
<sup>396</sup> cles produced in the proton collisions by using magnetic fields, silicon detectors,  
<sup>397</sup> sampling calorimeters, and gaseous wire detectors. It is located approximately  
<sup>398</sup> 100 m underground at Point-1 around the LHC beam line and weighs 7000 metric  
<sup>399</sup> tons. The detector is 46 m long, 25 m high, 25 m wide as shown in Figure 5.2.  
<sup>400</sup> The detector can be divided into three subsystems: the Inner Detector (ID), the  
<sup>401</sup> Calorimeters, and the Muon Spectrometer (MS). Figure 5.3 shows an overview of  
<sup>402</sup> how different particles interact in the detector.

**Figure 5.1:** Big picture layout of ATLAS detector. Natasha: write more

**Figure 5.2:** Big picture layout of ATLAS detector. Natasha: write more

**Figure 5.3:** A simplified schematic of how different particles interact and are detected within ATLAS.

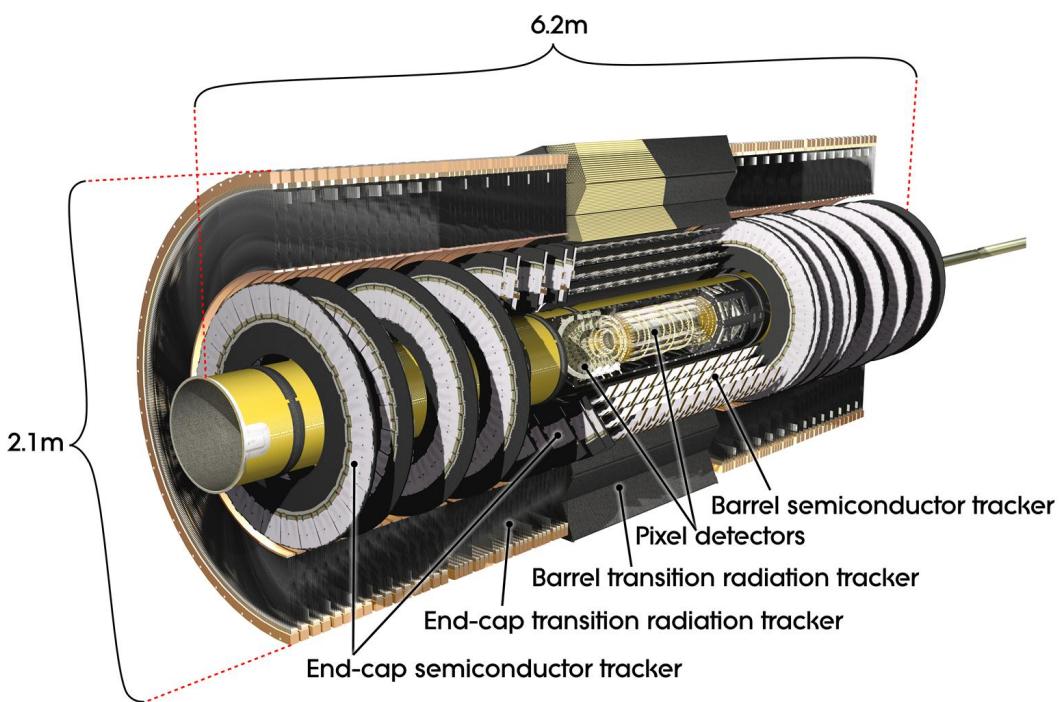

## 403 5.1 Coordinate System

404 The trajectory of particles within ATLAS is measured relative to the nominal  
 405 interaction point. The  $z$ -axis points along the beam line, such that when the  
 406 LHC is viewed from above, the counter-clockwise circulating beam points along  
 407 the positive- $z$  direction. The  $x - y$  plane is transverse to the beam line, with the  
 408 positive  $x$ -axis pointing towards the center of the LHC ring. The positive  $y$ -axis  
 409 points vertically upward. The azimuthal angle,  $\phi$ , is the angular distance about

410 the  $z$ -axis, with  $\phi = 0$  along the  $x$ -axis. The polar angle from the  $z$ -axis is denoted  
411 as  $\theta$ . However, this quantity is not Lorentz invariant, like rapidity,  $y = \frac{1}{2} \ln \frac{E+p_z}{E-p_z}$ ,  
412 where  $E$  is the energy of the particle considered, and  $p_z$ , is it's momentum along  
413 the  $z$ -axis. Pseudo-rapidity is preferred as  $\Delta\eta$  is invariant under boosts along  $z$   
414 and particle production is approximately invariant under  $\eta$ . For massless particles,  
415 rapidity and a related quantity, pseudorapidity, are the identical. The pseudora-  
416 pidity is defined as:  $\eta = -\ln \tan(\frac{\theta}{2})$ . This quantity is preferred as it is purely a  
417 geometric quantity, independent of particle energy. Angular separation between  
418 particles in ATLAS are given by  $\Delta R = \sqrt{\Delta\eta^2 + \Delta\phi^2}$ . The distance from the  
419 beamline is given by  $r = \sqrt{x^2 + y^2}$

## 420 5.2 Inner Detector

421 The Inner Detector (ID) was designed to identify and reconstruct vertices,  
422 distinguish pions from electrons, and measure the momentum of charged particles.  
423 The ID uses three different technologies for particle reconstruction: the Pixel  
424 Detector, Semiconductor Tracker (SCT), and the Transition Radiation Tracker  
425 (TRT), shown in Figure 5.4 and 5.5. The entire ID is immersed in a 2T solenoidal  
426 magnetic field parallel to the  $+z$ -axis, causing charged particles to bend in the  
427 transverse-plane, allowing particle momentum measurements.

**Figure 5.4:** Layout of ATLAS Inner Detector

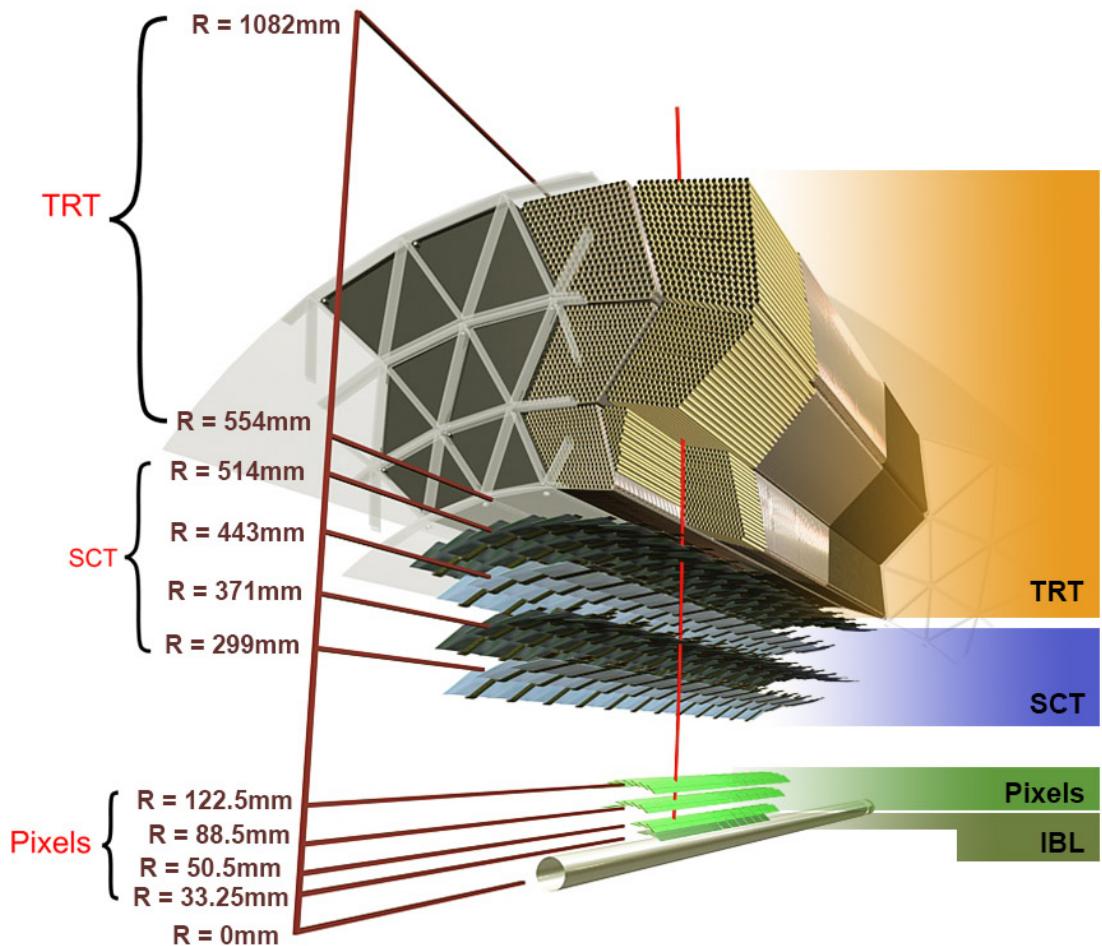

Figure 5.5: Layout of ATLAS ID Barrel System.

428 **5.2.1 Pixel Detector**

429 The pixel detector consists of four barrel layers between  $r = 32.7$  and  $122.5$   
430 mm, extending to  $|z| = 400.5$  mm. The innermost pixel barrel, the Insertable  
431 b-Layer (IBL), only extends to  $|z| = 332$  mm. The pixel detectors closer to  
432 the beam line (larger  $\eta$  values) consists of six parallel cylindrical rings of pixel  
433 detectors transverse to the beam line. The entire pixel detector consists of 1744  
434 identical pixel sensors each with 46080 readout channels, totaling about 80 million  
435 individual pixels. Most of the pixel sensors are  $50 \times 400\mu\text{m}^2$ . Each pixel has a  
436 position resolution of  $14\mu\text{m}$  in  $\phi$  and  $115\mu\text{m}$  in the  $z$  direction.

437 **5.2.2 Semiconductor Tracker**

438 The SCT is located outside the pixel detector and has the same barrel and  
439 endcap geometry as the pixel detector. SCT sensors are  $80\mu\text{m} \times 12$  cm with  
440 a  $80\mu\text{m}$  strip pitch. In the barrel the strips are parallel to the  $z$ -axis and are  
441 segmented in  $\phi$ . In the endcaps, the strips extend radially. Sensors are grouped in  
442 modules containing two layers of strips rotated 40 mrad with respect to each other.  
443 This offset allows for the two-dimensional position of a track to be determined by  
444 identifying the crossing point of the strips that registered a hit. SCT modules  
445 measure tracks with an accuracy of  $17\mu\text{m}$  in  $r - \phi$  and  $580\mu\text{m}$  in  $z(r)$  in the  
446 barrel (end-cap) region.

447 **5.2.3 Transition Radiation Tracker**

448 The transition radiation tracker (TRT), enveloping the SCT, is a gaseous  
449 straw-tube tracker mainly used for electron/pion track separation. Each straw  
450 is 4 mm in diameter and filled with a Xe- $\text{CO}_2$ - $\text{O}_2$  gas mixture. An anode wire  
451 at the center of the straw is held a ground potential, while the walls of the straw

452 are kept at -1.4kV. When a charged particle passing through the TRT ionizes the  
453 gaseous mixture, the resulting ions form an avalanche on the anode wire with a  
454 gain of  $\sim 10^4$ . The signal from the anode wire is then digitized and amplified.  
455 Signals passing a low threshold cutoff are used to distinguish noise from tracks.  
456 Signals passing a high threshold cutoff are sensitive to transition radiation (TR).  
457 TR photons are emitted when charged particles pass between materials with dif-  
458 ferent dielectric constants. The probability that a charged particle with energy  $E$   
459 and mass  $m$  passing between two materials emits a TR photon in the keV range  
460 is proportional to  $\gamma = E/m$ . In the TRT straws these often then convert via the  
461 photoelectric effect, causing a large avalanche triggering the high-threshold. Since  
462 electrons have a smaller mass than pions, electron tracks are more likely to trig-  
463 ger the high threshold. This then provides discrimination between electrons and  
464 charged hadrons.

465 The barrel region of the TRT extends from  $r = 563\text{-}1066$  mm and  $|z| < 712$   
466 mm. Barrel Straws are 144 cm long (divided  $\sim \eta \approx 0$ ) and orientated parallel to  
467 the beam direction. End-cap straws extend radially and are 37 cm long. There  
468 are 53,544 straws in the barrel and 160,000 straws in the end-caps. Radiator mats  
469 of polypropylene/polyethylene fibers in the barrel are aligned perpendicular to the  
470 barrel straws (with holes for the straws to pass through). In the end-cap region,  
471 radiator foils are layered between the radial TRT straws.

472 The width of the signal pulse is sensitive to the distance between the charged  
473 particle track and the anode wire and allows for a hit resolution of  $130\mu\text{m}$ . The  
474 TRT extends to  $|\eta| = 2.0$  and provides about 36 hits per track.

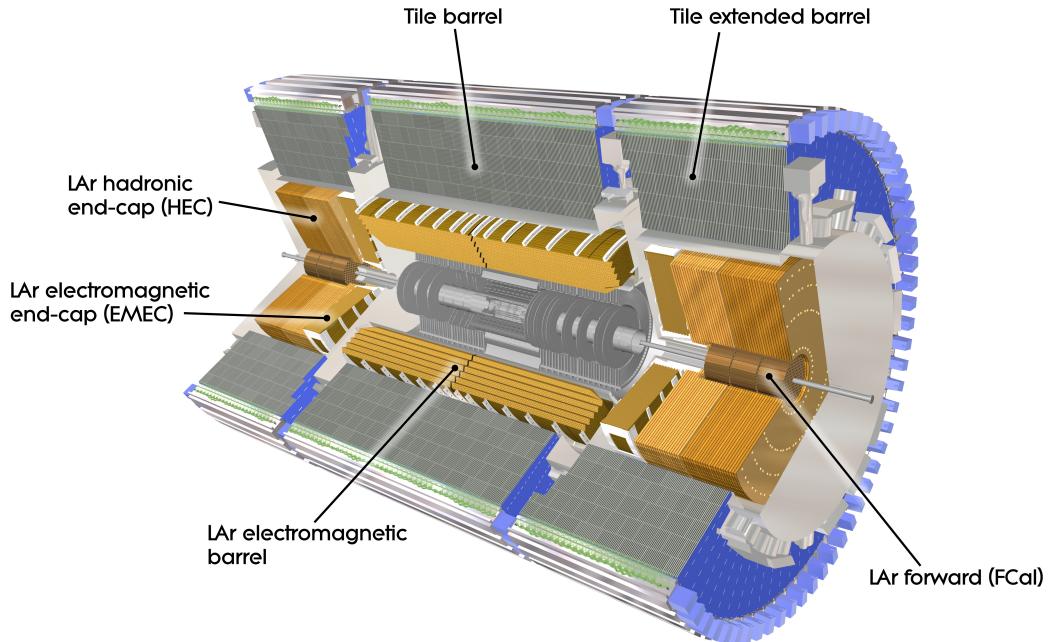

475 **5.3 Calorimeters**

476 The ATLAS electromagnetic and hadronic calorimeters (EMC and HCAL,  
477 respectively) absorb and measure the energy of high energy hadrons, photons,  
478 and electrons with  $|\eta| < 4.9$ . Both systems use sampling calorimeters which  
479 consist of alternating layers of dense absorbing and active layers. In the absorbing  
480 layer particles interact and lose energy, creating showers. These showers are then  
481 detected and measured in the active layer. The amount of charge measured in the  
482 active material scales with the energy of the incident particle, and thus provides a  
483 measurement of the particle's energy. An overview of the layout of the calorimeter  
484 system is shown in Figure 5.6.

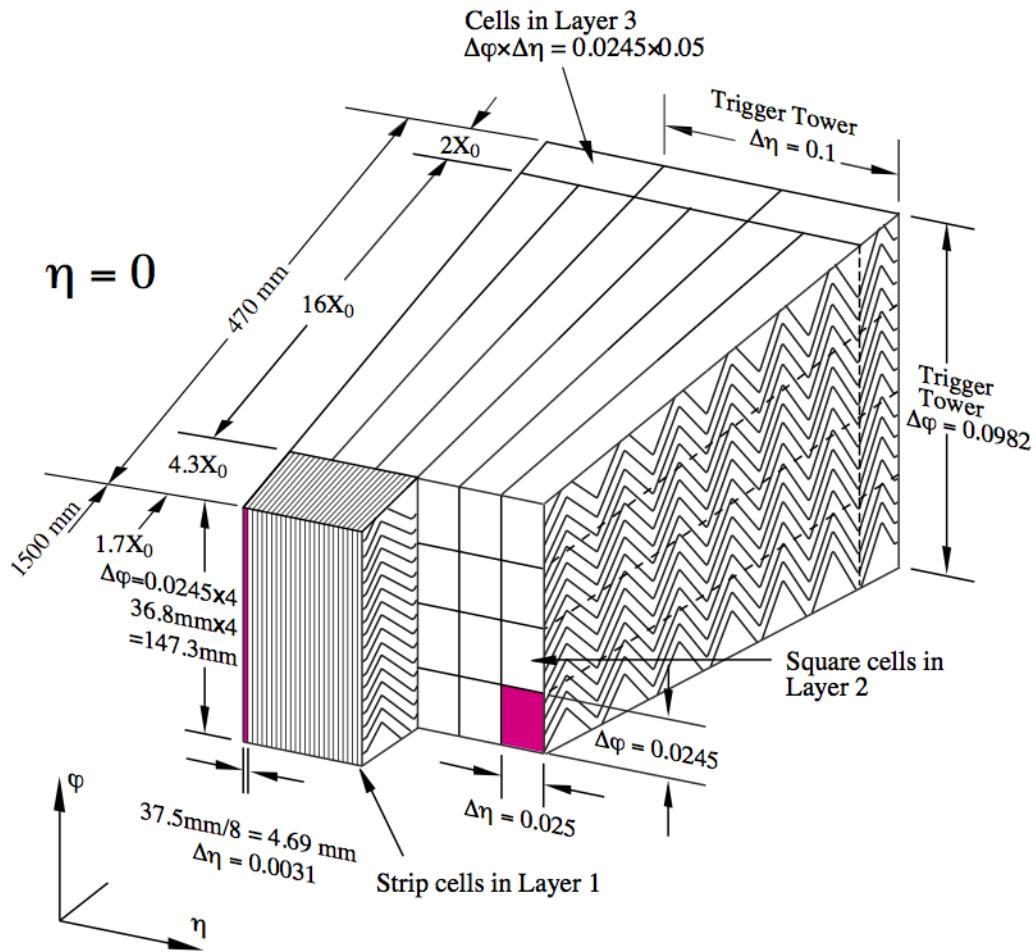

485 The EMC measures and contains the energy of electromagnetically interacting  
486 particles with 170k channels. It consists of layered accordion-shaped Lead ab-  
487 sorber plates and electrodes immersed in liquid Argon. Using accordion-shaped  
488 electrode and absorbers ensures  $\phi$  symmetry and coverage. The EMC is com-  
489 posed of a barrel part ( $|\eta| < 1.475$ ), two end-caps ( $1.375 < |\eta| < 3.2$ ), and a  
490 presampler ( $|\eta| < 1.8$ ). The presampler, containing only liquid Argon, corrects  
491 for upstream energy losses of electrons and photons. The EMC barrel is segmented  
492 into three layers. The first layer has finest segmentation with readout cells ex-  
493 tending  $\Delta\eta \times \Delta\phi = 0.025/8 \times 0.1$ . This provides a precise shower measurements  
494 used to separate prompt photons from  $\pi^0 \rightarrow \gamma\gamma$  decays. The second layer has  
495 coarser segmentation and is approximately 16 radiation lengths long. A radiation  
496 length is the average distance an electron travels before losing all but  $1/e$  of its  
497 energy to bremsstrahlung. The last layer is the most coarse and measures the tail  
498 of the electromagnetic shower. A schematic of the ECAL is shown in Figure 5.7.

499 The hadronic calorimeter located outside the EMC and is used to contain  
500 and measure the energy of hadronically interacting particles. It consists of a tile

501 calorimeter (TileCal), hadronic end-cap calorimeter (HEC), and liquid Argon for-  
 502 ward calorimeter (FCAL). TileCal is located behind the LAr EMC and uses steel  
 503 absorbers and liquid Argon as the active material. TileCal consists of three barrel  
 504 layers in the central and forward regions, extending up to  $|\eta| < 1.7$ . Radiated  
 505 photons from the steel tiles are collected via wavelength-shifting fibers connected  
 506 to photomultiplier tubes, as shown in Figure 5.8. The HEC lies behind the EMC  
 507 endcap wheels. It uses copper absorbers and liquid Argon as the active material  
 508 and covers  $1.5 < |\eta| < 3.2$ . Finally, the FCAL covers  $3.1 < |\eta| < 4.9$  and consists  
 509 of three modules all using liquid Argon as the active material. The first module  
 510 uses copper absorber and was designed for electromagnetic measurements. The  
 511 second and third modules consist of tungsten absorber and are used to measure  
 512 the kinematics of hadronically interacting particles. A schematic of the HCAL is  
 513 shown in Figure 5.8.

**Figure 5.6:** Overview of ATLAS electromagnetic and hadronic calorimeters.

**Figure 5.7:** Schematic of ECAL.

**Figure 5.8:** Schematic of HCAL.

514 The energy resolution of the calorimeter subsystems are:

515 
$$\frac{\sigma_E}{E} = \frac{10\%}{\sqrt{E}} \oplus 0.7\% \text{ EMC}$$

516 
$$\frac{\sigma_E}{E} = \frac{50\%}{\sqrt{E}} \oplus 3\% \text{ hadronic barrel -Natasha check if barrel and end-cap truly}$$

517 have same energy resolution

518 
$$\frac{\sigma_E}{E} = \frac{50\%}{\sqrt{E}} \oplus 3\% \text{ hadronic end-cap}$$

519 
$$\frac{\sigma_E}{E} = \frac{100\%}{\sqrt{E}} \oplus 10\% \text{ hadronic end-cap}$$

## 520 5.4 Muon Spectrometer

521 The muon spectrometer (MS) is the outermost detector system in ATLAS.  
522 Muons with a  $p_T > 4$  GeV are energetic enough to reach the MS. To measure the  
523 momentum of these muons two barrel and end-cap toroid magnets are used covering  
524  $|\eta| < 1.4$  and  $1.6 < |\eta| < 2.7$ . For  $1.4 < |\eta| < 1.6$ , a combination of the barrel  
525 and end-cap toroidal magnetic fields bend muon trajectories. The detector in the  
526 barrel region form three concentric rings at  $R = 5, 7.5, 10$ m and are segmented  
527 in  $\phi$  to accommodate the magnets. The end-cap region consists of three circular  
528 planes perpendicular to  $z$  and located at  $|z| = 7.4, 14, 21.5$ m from the interaction  
529 region. An additional detector at  $|z| = 10.8$ m covers the transition region between  
530 the barrel and end-cap.

531 The MS consists of four subsystems: Monitored Drift Tubes (MDT), Cathode  
532 Strip Chambers (CSC), Resistive Plate Chambers (RPC), and Thin Gap Cham-  
533 bers (TGC). The first two subsystems are used primarily for measuring muon track  
534 parameters, while the RPC and TGC subsystems are used for muon triggering.  
535 A schematic of this system is shown in Figure 5.9.

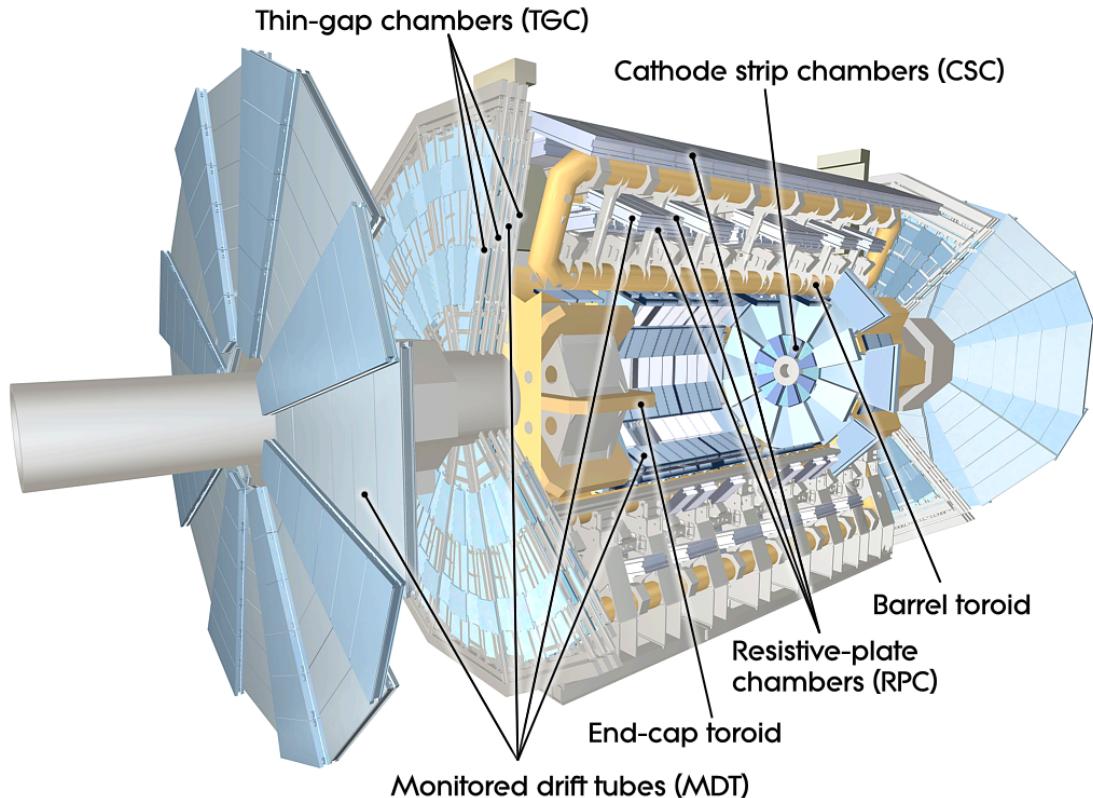

536 The MDT subsystem consists of precision tracking chambers for  $|\eta| < 2.7$ ,  
537 except for the inner most end-cap layer ( $2.0 < |\eta| < 2.7$ ), where CSCs are used.  
538 The basic unit of MDT chambers are thin walled Aluminum tubes with a diameter  
539 of 3 cm and length of 0.9-6.2 m. These tubes are filled with a mixture of Ar-CO<sub>2</sub>  
540 gas with a 50μm W-Rn wires running down the center of the tube which is kept at  
541 3080 V. Since the maximum drift time of these chambers is ∼ 700 ns, they are not  
542 used for triggering. MDT chambers consist of 3-4 layers of tubes mounted on a  
543 rectangular support system, as seen in Figure 5.10, orientated along  $\phi$  to measure  
544 the coordinate in the bending plane of the magnetic field with a resolution of 35  
545 μm.

546        The MDT subsystem can only handle hit rate below 150Hz/cm<sup>2</sup>. For this  
547 reason, CSCs are used in the innermost end-cap layer where hit rates are larger.  
548 CSCs can handle hit rates up to 1000Hz/cm<sup>2</sup>. CSC are multiwire proportional  
549 chambers. These chambers are filled with a Ar-CO<sub>2</sub> gas mixture and evenly spaced  
550 wires kept at 1900 V. These wires are orientated in the radial direction but not  
551 read out. Instead on one side of the cathode are copper strips parallel to the wires,  
552 measuring  $\eta$ , while on the other side of the cathode are strips parallel to the wires  
553 measuring  $\phi$ . The width between strips is approximately 1.5 mm providing a  
554 resolution of 60  $\mu$ m in the bending-plane and 5 mm in the non-bending plane.

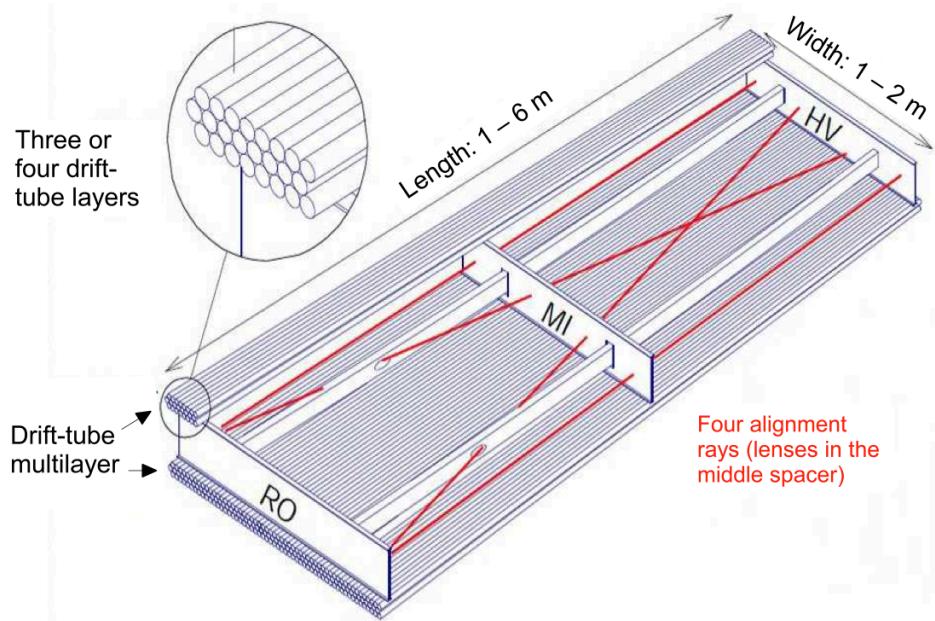

555        Since the CSC and MDT systems do not poor time resolution, the RPC and  
556 TGC systems are used for triggering. The RPC system is used in the barrel region  
557 ( $|\eta| < 1.05$ ). RPC consist of two parallel resistive plates separated by a 2 mm  
558 insulated spacer with 100 mm spacing kept at 9.8 kV 5.11. A gaseous mixture of  
559 C<sub>2</sub>H<sub>2</sub>F<sub>4</sub>, C<sub>4</sub>H<sub>10</sub>, and SF<sub>6</sub> fills the space between the two plates. Metallic strips  
560 on the outer faces of the plates are used to read out signals produced by the  
561 gas ionizing. The middle barrel layer consists of two layers of RPCs on either  
562 side of the MDT layer and one layer on the outermost MDT layer. Each layer  
563 contains two orthogonal sets of metallic strips providing  $\eta$  and  $\phi$  measurements.  
564 The timing resolution of RPCs is 1.5 ns, and therefore may be used to identify  
565 bunch crossings.

566        Finally, the TGCs are used in the end-cap regions and primarily used to pro-  
567 vide L1 trigger decisions and  $\phi$  measurements. TGCs are multi-wire proportional  
568 chambers consisting of arrays of gold-coated tungsten wires placed between two  
569 cathode planes. These wires are separated by 1.8 mm and cathodes are 1.4 mm  
570 from the wires. Orthogonal to the wires, on the opposite side of the cathode plane  
571 are copper strips held at 2900 V. The chambers are filled with a mixture of CO<sub>2</sub>

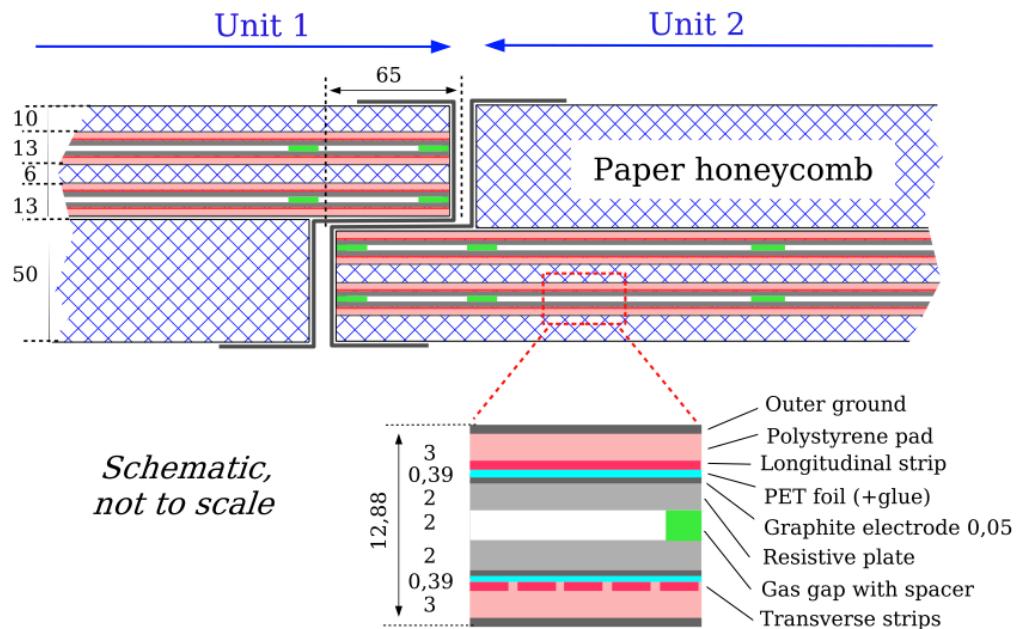

572 and n-pentane gas, the latter acts as a quenching gase to prevent avalances initiated  
573 by secondary  $\gamma$ -rays from the primary avalanche. Figure 5.12 is a schematic  
574 of a TGC. The timing resolution of TGCs is less than 25 ns and therefore are used  
575 for bunch crossing measurements.

## 576    5.5 Magnet System

577    A particles with charge,  $q$ , and velocity  $v$ , moving in magnetic field,  $B$ , ex-  
 578    periences a force,  $F = qv \times B$ . This force can cause charged particles to have a  
 579    curved trajectory in magnetic fields, which the ID and MS use to determine the  
 580    particles  $p_T$ . The central solenoid provides the magnetic field for the ID and the  
 581    toroidal magnets provide the magnetic field for the MS.

582    The layout of the magnet system is shown in Figure 5.13. The central solenoid  
 583    consists of a single-layer Al-stabilized NbTi conductor coil wound inside an Al

584 support cylinder. The solenoid is 5.8 m long, 50 cm thick and has an inner radius  
585 of 1.23 m. It is cooled to 4.5 K to reach superconducting temperatures and shares  
586 the liquid argon calorimeter vacuum vessel to minimize material in the detector.  
587 A current of 7.730kA produces a 1.998 T solenoidal magnetic field, pointing in  
588 the  $+z$  direction.

589 The toroidal magnet system consists of a barrel and two end-cap toroidal  
590 magnets used to a magnetic field outside the calorimeters that is orientated along  
591  $\phi$ . Each barrel toroid is 25.3 m long with an inner and outer diameter of 9.4 and  
592 20.1 m and weighs 830 tonnes. Endcap toroids are 5 m long with an inner and  
593 outer radius of 1.65 and 10.7 m. Both toroid systems use Al-stabilized Nb/Ti/Cu  
594 conductors. The magnetic field strength of the barrel and endcap regions are 0.5  
595 and 1 T.

**Figure 5.13:** Layout of ATLAS magnet systems.

## 596 5.6 Trigger System

597 Since collisions occur every 25 ns and reading out all detector channels and  
598 storing that information is not currently feasible (saving 60 million megabytes per

599 second), the majority of events are not kept for analysis. ATLAS uses a multi-  
600 stage trigger system to select approximately 1,000 of the 1.7 billion collisions that  
601 occur each second (corresponding to a rate of 1 kHz from the 40 MHz proton  
602 collision rate). The first stage of the trigger system is the hardware level (L1)  
603 trigger. This trigger reduces the event rate to  $\sim$ 100 kHz by identifying Regions-  
604 of-Interest (ROIs) containing high  $p_T$  leptons, photons, jets, or  $E_T^{miss}$  by using  
605 information from RPCs, TGCs, and calorimeters to make a  $2.5 \mu\text{s}$  decision. This  
606 information is then passed to a high-level trigger (HLT) which further decreases  
607 event rates to  $\sim 1$  kHz. The HLT uses finer granularity measurements from the  
608 MS and ID to perform simplified offline reconstruction to decide which events to  
609 keep.

## **Part III**

610

## **Method**

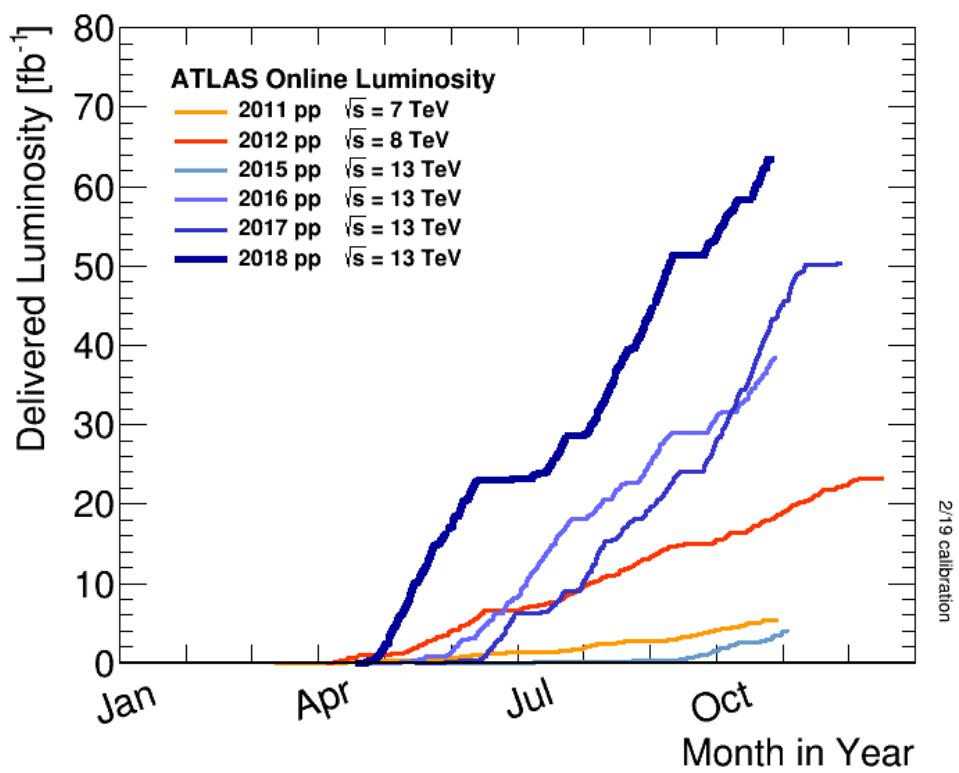

611

612 **Chapter 6**

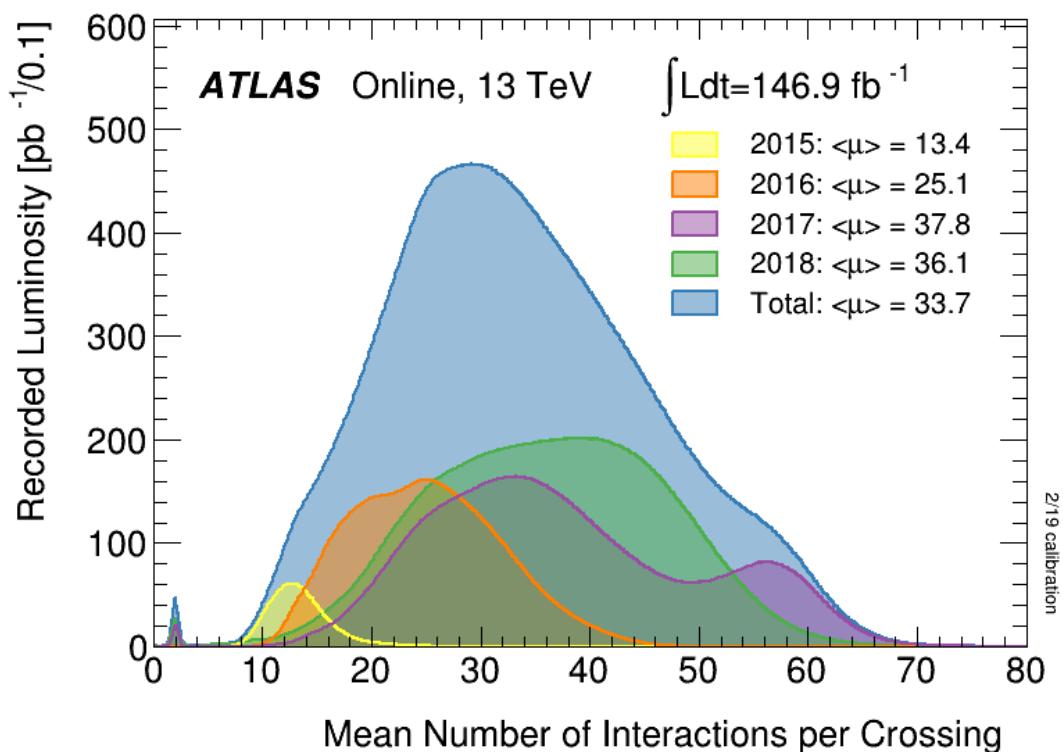

613 **Dataset and Simulated Samples**

614 **6.1 Dataset**

615 This analysis uses  $pp$  collision data collected from 2015 to 2018 at  $\sqrt{s} = 13$   
616 TeV, corresponding to 139/fb of data as shown in Figure 6.1 and 6.2. From this  
617 dataset, only those events in which the tracker, calorimeters, and muon spectrom-  
618 eter have good data quality are used. For a given event, the solenoid and toroidal  
619 magnets must also be operating at their nominal field strengths. In addition to  
620 this, events must pass further quality checks to reject events where detector sub-  
621 systems may have failed. These selections reject events that contain LAr noise  
622 bursts, saturation in the electromagnetic calorimeter, TileCal errors, and failures  
623 in event recovery due to tracker failures. Events with information missing from  
624 subsystems (usually due to busy detector conditions) are rejected. Events must  
625 also contain a primary vertex with at least two associated tracks, where the pri-  
626 mary vertex is selected as the vertex with the largest  $\sum p_T^2$  over tracks associated  
627 with the vertex and  $p_T > 0.5$  GeV.

**Figure 6.1:** Integrated luminosity for data collected from ATLAS from 2011 - 2018

**Figure 6.2:** Mean number of interactions per crossing for data collected from ATLAS from 2011 - 2018

628 **6.2 Simulated Samples**

629 Samples are simulated in order to model backgrounds, evaluate signal ac-  
630 ceptance, optimize event selection and estimate systematic and statistical uncer-  
631 tainties. The dominant backgrounds for this analysis are  $W/Z + \text{jets}$ , diboson  
632 ( $WZ/WW$ ),  $t\bar{t}$ , single top and multijet production.

633  $W/Z+\text{jet}$  events are simulated using Sherpa 2.2.1 at NLO [cite [29]] and merged  
634 with the Sherpa parton shower using the ME+PS@NLO prescription [11]. These  
635 events are then normalized to NNLO cross sections. The  $t\bar{t}$  and single-top back-  
636 grounds are generated with Powheg-Box with NNPDF3.0NLO PDF sets in the  
637 matrix element calculation [cite[35]]. For all processes, the parton shower, frag-  
638 mentation, and underlying event are simulated using Pythia 8.320 with the A14  
639 tune set[cite[ATL-PHYS-PUB-2014-02]]. Diboson processes are generated using  
640 Sherpa 2.2.1.

641 Signal samples are simulated using MadGraph 5-2.2.2 [cite 42] and Pythia  
642 8.186 with NNPDF230LO. RS Graviton samples are generated with  $k/M_{PL}=1$ .  
643 HVT Model A (B) samples are simulated with  $g_V = 1(3)$ , as the difference in the  
644 width of the samples is smaller than detector resolution. Model C is generated by  
645 setting  $g_H = 1$  and  $g_f = 0$  to model VBF production of HVT bosons. Signals are  
646 generated for masses between 300 GeV and 6 TeV.

647 **6.3 Object Selection**

648 **6.3.1 Electrons**

649 Electrons are reconstructed from electromagnetic showers in the LAr EM  
650 calorimeter. During reconstruction cells of  $\Delta\eta \times \Delta\phi = 0.025 \times 0.025$  are grouped  
651 into  $3 \times 5$  clusters. These clusters are then scanned for local maxima that seed

652 electron clusters. These clusters must then be matched to ID track from the PV.  
653 This requirement minimizes non-prompt electron and fake electron backgrounds.  
654 Electrons must pass identification and isolation requirements. Electron identifica-  
655 tion (loose, medium, tight) classification is based on a multivariate discriminant  
656 that identifies electrons using a likelihood based method. For this analysis tight  
657 electrons are used. Electrons are also required to be isolated. The electrons are  
658 considered isolated if the quotient of the sum of the transverse momentum (of  
659 calorimeter energy deposits) in a cone around the electron of size  $\Delta R = 0.2$  and  
660 the transverse momentum of the electron to be less than  $0.015 * p_T$  or 3.5 GeV,  
661 whichever is smaller. This requirement rejects non-prompt photons and other  
662 fake leptons. Electrons in this analysis are also required to have  $p_T > 30$  GeV and  
663  $|\eta| < 2.47$ . Electrons are also required to have  $p_T > 30$  GeV.

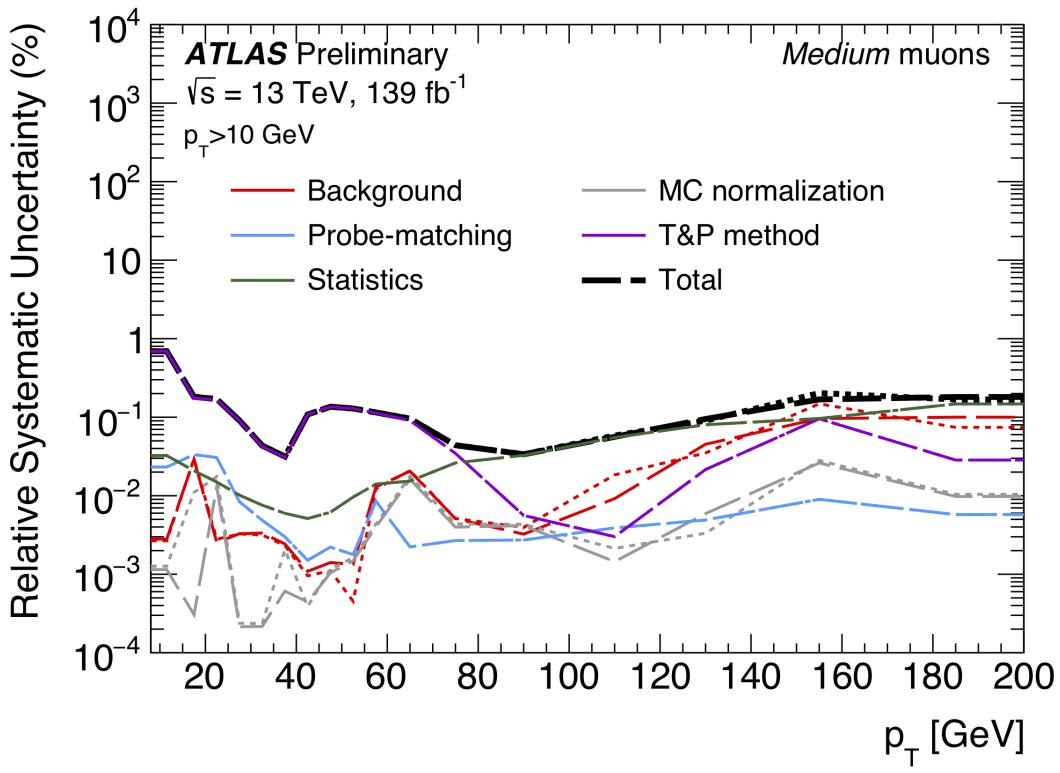

664 Electrons are calibrated to determine data-driven scale factors from  $J/\Psi \rightarrow ee$ ,  
665  $Z \rightarrow ee$ ,  $Z \rightarrow \ell\ell\gamma$  processes. These corrections account for the non-uniform  
666 response of the detector by introducing modeling and reconstruction uncertainties.

### 667 6.3.2 Muons

668 As muons traverse the entire detector, they are reconstructed from ID and MS  
669 tracks. For this analysis the muon identification and isolation working points are  
670 chosen to minimize the contributions from non-prompt muons. Towards this end,  
671 the medium muon identification working point is used. For this working point,  
672 two types of reconstructed muons are used: combined and extrapolated muons  
673 (CB and ME, respectively). For CB muons, ID and MS tracks are reconstructed  
674 independently and a combined track fit is performed by adding or removing MS  
675 tracks to improve the fit quality. ME muons are reconstructed from only MS  
676 tracks with hits in at least two layers, which ensures the track originates from the

677 PV. ME muons extend the acceptance for muon reconstruction outside the ID  
678 from  $2.5 < |\eta| < 2.7$ . The medium identification working point uses CB and ME  
679 tracks. CB tracks must have at least 3 hits in two MDT layers. ME tracks are  
680 required to have at least three MDT/CSC hits. To further minimize contributions  
681 from fake muons, the selected muons are required to be isolated from other tracks,  
682 as muons from  $W, Z$  decays are often isolated from other particles. To insure the  
683 selected muons are isolated, the scalar sum of the transverse momentum of tracks  
684 in a cone of  $\Delta R = 0.3$  compared to the transverse momentum of the muon must  
685 be less then 0.06. Muons are also required to have  $p_T > 30$  GeV.

686 Muons are calibrated using well-studied resonances  $J/\Psi \rightarrow \mu\mu$  (low- $p_T$ ),  $Z \rightarrow$   
687  $\mu\mu$  (high- $p_T$ ). Figure 6.3 shows the combined muon  $p_T$  uncertainty from this  
688 calibration. The total systematic uncertainty is less then 1% for all  $p_T$  ranges  
689 considered in this analysis.

**Figure 6.3:** This figure shows the breakdown of the muon reconstruction efficiency scale factor measured in  $Z \rightarrow \mu\mu$  as a function of  $p_T$  [4].

### 6.3.3 small-R jets

Small-R jets are used to reconstruct the hadronically decaying  $W/Z$  candidates in the resolved analysis and VBF jets. These jets are less boosted and therefore spatially separated and reconstructed separately. These jets are constructed from topologically connected clusters of calorimeter cells (topoclusters), seeded from calorimeter cells with energy deposits significantly above the noise threshold. These cells are then used as inputs to the  $anti-k_t$  algorithm [12] with a distance = 0.4, here called small-R jets. These jets are calibrated to compensate and account for biases from jet reconstruction.

The jet energy is calibrated sequentially as shown in Figure 6.4. After the jet

700 direction is corrected to point to the PV, the energy of the jet is corrected. First,  
701 the jet energy is corrected to account for pileup contributions based on the  $p_T$  and  
702 area of the jet (these corrections are extracted from a  $pp \rightarrow jj$  sample). Following  
703 this, another pileup correction is applied that scales with  $\mu$  and  $N_{PV}$ .

704 Then, MC-based corrections are applied that are meant to transform the jet  
705 energy and  $\eta$  back to truth level. Therefore, these corrections account for the  
706 non-compensating nature of the ATLAS calorimeters and inhomogeneity of the  
707 detector. Following this the Global Sequential Calibration is applied that reduces  
708 flavor dependence and jet that deposit energy outside the calorimeters. Finally,  
709 in-situ corrections are applied that account for differences in jet responses between  
710 data and simulation ( $\gamma/Z+jet$  and multijet samples are used). These differences  
711 can be due to mismodelling of the hard scatter event, pile-up, jet formation, etc.

712 Jet used in this analysis must have  $p_T > 30$  GeV and  $|\eta| < 2.5$ . To further  
713 reduce fake jets the jet-vertex-tagger (JVT) is used to reject pile-up jets [cite 43  
714 P]. The JVT uses two track-based variables, corrJVF and  $R_{p_T}$  to calculate the  
715 likelihood that the jet originated from the PV. The corrJVF compares the scalar  
716 sum of the  $p_T$  of tracks associated with the jet and PV to the scalar sum of the  
717  $p_T$  of tracks associated with the jet. This variable also includes a correction that  
718 reduces the dependency of corrJVF with the number of reconstructed vertices in  
719 the event. The other discriminant,  $R_{p_T}$ , is given by the ratio of the scalar sum  
720 of the  $p_T$  of tracks associated with the jet and PV to the  $p_T$  of the jet. Both of  
721 these variables peak around zero for pileup jets, as these jets are unlikely to have  
722 tracks associated with the PV. JVT cuts are applied to all jets with  $p_T > 120$   
723 GeV. Central jets ( $|\eta| < 2.4$ ) are required to have a  $JVT > 0.59$  and forward jets  
724 ( $2.4 < |\eta| < 2.5$ ) are required to have  $JVT > 0.11$ .

725 To further reject fake jets, jets must pass quality requirements based on the

726 following variables ([cite P42]):

727 -  $f_Q^{LAr}$ : fraction of energy of jet's LAr cells with poor signal shape

728 -  $f_Q^{HEC}$ : fraction of energy of jet's HEC cells with poor signal shape

729 -  $E_{neg}$ : sum of cells with negative energy

730 -  $f_{EM}$ : fraction of jet's energy deposited in EM calorimeter

731 -  $f_{HEC}$ : fraction of jet's energy deposited in HEC calorimeter

732 -  $f_{max}$ : maximum energy fraction in any single calorimeter layer

733 -  $f_{ch}$ : ratio of the scalar sum of the  $p_T$  of a jet's charged tracks to the jet's  $p_T$

734 Jets selected for the resolved analysis must pass one of the following criteria:

735 -  $f_{HEC} > 0.5$  and  $|f_Q^{HEC}| > 0.5$  and  $\langle Q \rangle > 0.8$

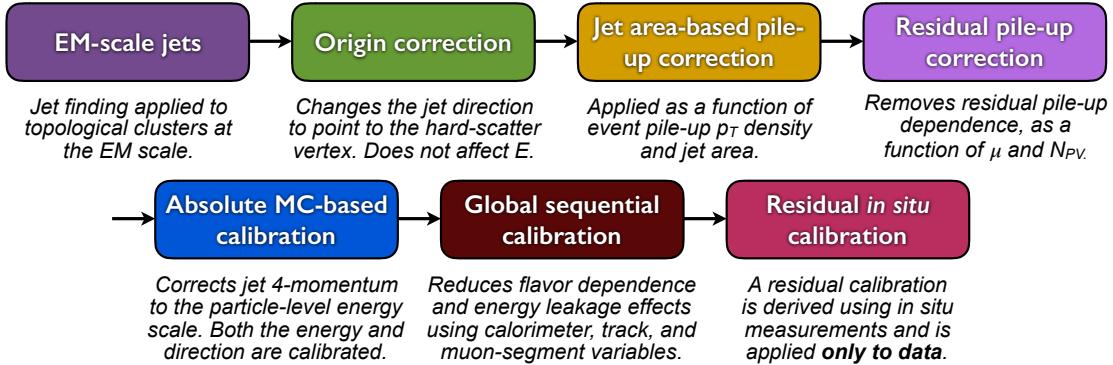

736 -  $|E_{neg}| > 60$  GeV

737 -  $f_{EM} > 0.95$  and  $f_Q^{LAr} > 0.8$  and  $\langle Q \rangle > 0.8$  and  $|\eta| < 2.8$

738 -  $f_{max} > 0.99$  and  $|\eta| < 2$

739 -  $f_{EM} < 0.05$  and  $f_{ch} < 0.05$  and  $|\eta| < 2$

740 -  $f_{EM} < 0.05$  and  $|\eta| > 2$

**Figure 6.4:** [6] This diagram shows the calibration stages for EM jets.

### 741 6.3.4 large-R jets

742 Large-R ( $\Delta R = 1.0$ ) jets are used to reconstruct the high- $p_T W/Z \rightarrow qq$  candi-  
 743 dates in the merged analysis. Track-Calorimeter Clusters (TCCs) are used to reconstruct  
 744 these jets [cite ANA 50]. These jets are constructed via a pseudo particle flow  
 745 method using ID tracks matched to calorimeter clusters. The angular resolution  
 746 of the calorimeter degrades sharply with jet  $p_T$ , but the jet energy resolution im-  
 747 proves. The tracker has excellent angular resolution improves with  $p_T$ . Therefore,  
 748 by matching tracks to jets, TCCs have more precise energy and angular resolution  
 749 the jets constructed from calorimeter information only. These jets are required to  
 750 have  $p_T > 200$  GeV,  $|\eta| < 2.0$  and  $m_J > 50$  GeV.

751 TCC jets are trimmed as detailed in [cite ANA 45], which suppresses pileup  
 752 and soft radiation in the jet, the jet mass is calculated as the four-vector sum  
 753 of the jet's constituents (assuming massless constituents). The jet mass peaks  
 754 around the  $W/Z$  boson mass for  $W/Z \rightarrow qq$  jets, and more broadly for quark and  
 755 gluon induced jets.

756 These jets are then tagged as  $W/Z$  jets if they pass the jet mass and  $D_2$   
 757 cuts. The jet substructure variable  $D_2$  is given by the ratio of energy correlation  
 758 functions based on energies and pair-wise angles of a jet's constituents [cite ANA

759 46, 47]:

$$D_2^{\beta=1} = E_{CF3} \left( \frac{E_{CF1}}{E_{CF2}} \right)^3 \quad (6.1)$$

760 Where the energy correlation functions are defined as:

$$E_{CF1} = \sum_i p_{T,i} \quad (6.2)$$

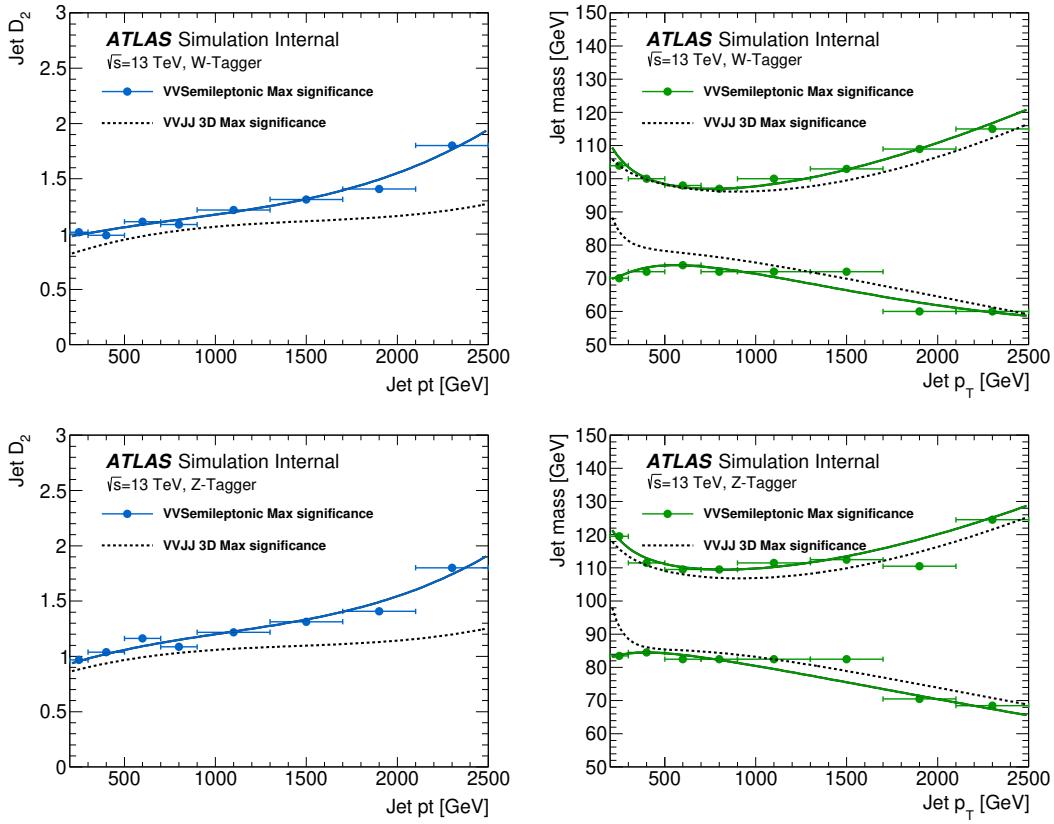

761

$$E_{CF2} = \sum_{ij} p_{T,i} p_{T,j} \Delta R_{ij} \quad (6.3)$$

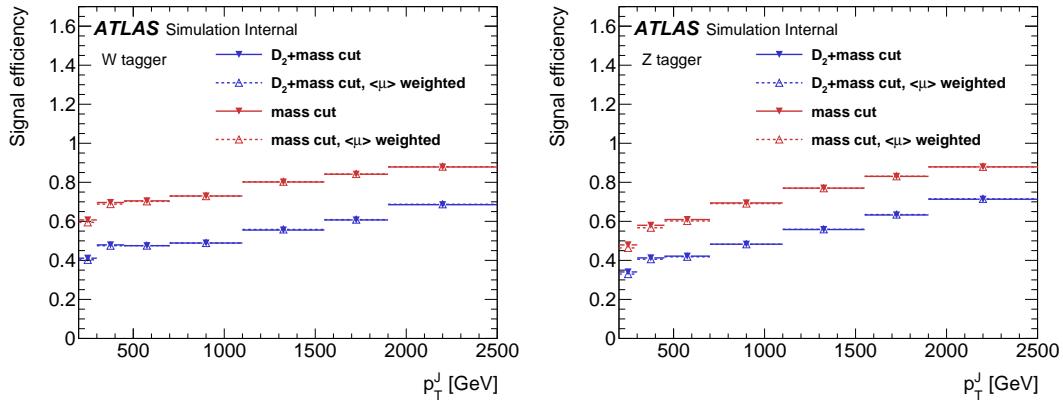

762

$$E_{CF3} = \sum_{ijk} p_{T,i} p_{T,j} p_{T,k} \Delta R_{ij} \Delta R_{jk} \Delta R_{ki} \quad (6.4)$$

763 A two-dimensional optimization of the jet mass and  $D_2$  thresholds was per-  
764 formed to provide maximum sensitivity for this analysis. Figure 6.5 shows the  
765 optimized thresholds on  $D_2$  and jet mass as a function of  $p_T$ . Figure 6.6 shows  
766 the efficiency of the optimized  $W/Z$  taggers as a function of jet  $p_T$ .

**Figure 6.5:** The upper cut on  $D_2$  (a) and jet mass window cut i.e. the upper and lower boundary of the mass (b) of the  $W$ -tagger as a function of jet  $p_T$ . Corresponding values for  $Z$ -tagger are shown in (c) and (d). The optimal cut values for maximum significance are shown as solid markers and the fitted function as solid lines. Working points from  $VV \rightarrow JJ$ [ATLAS-HDBS-2018-31-002] is also shown as dashed lines as a reference. Natasha reword?

**Figure 6.6:** Natasha write caption

767 **6.3.5 Variable Radius jets**

768 Variable-radius (VR) track jets are used to identify b-quark induced jets within  
769 the catchment area of large-R jets [cite ANA 52]. These jets use a  $p_T$  dependent  
770 cone size defined as:

$$R_{eff}(p_{T,i}) = \frac{\rho}{p_{T,i}} \quad (6.5)$$

771 for building jets from ID tracks with an anti- $k_t$  algorithm. For this analysis  $\rho = 30$   
772 GeV and an upper and lower limit on cone size are set to 0.02 and 0.4, respectively.  
773 Collinear VR jets are possible, so track jets that are not separated by the the  
774 smaller jet's cone size are not used. These jets are also required to have  $p_T > 10$   
775 GeV and  $|\eta| < 2.5$ .

776 **6.3.6 MET/neutrinos**

777 As neutrinos are uncharged and colorless they do not leave tracks or jets in the  
778 detector. For this reason, neutrinos are reconstructed calculated the  $E_T^{miss}$ , the  
779 negative vector sum of  $p_T$  all the physics objects and an extra "soft" term. The  
780 "soft" term accounts for energy deposits not associated with any of the objects in  
781 the event. For this analysis the soft term is given by the sum  $p_T$  of all ID tracks  
782 not associated with objects in the event. The selected tracks must be matched to  
783 the primary vertex, which decreases pile-up contamination [cite G 217 218]. The  
784 tight working point is used [Natasha look up what this means].

785 **6.3.7 Jet Flavor Tagging**

786 To further classify events, the small radius jets originating from a b-quark are  
787 classified using a multivariate  $b$ -tagging algorithm (BDT), MC2c10 [cite G 210  
788 199]. This algorithm uses the impact parameters of the jet's ID tracks, secondary

789 vertices (if they exist), and reconstructed flight paths of  $b$  and  $c$  hadrons in the jet  
790 to determine if the jet was induced by a  $b$ -quark. For this analysis the 85% efficient  
791 working point of this algorithm is used to a fixed cut on the BDT discriminant  
792 that yields an 85% tag rate, and  $c$ ,  $\tau$ , and light-flavor jet rejection of 3, 8, and 34  
793 respectively in a simulated  $t\bar{t}$ .

794 **6.3.8 Overlap Removal**

795 Reconstructed jets and leptons in this analysis can arise from the same energy  
796 deposits. For instance, a cluster of energy from an electron can also be a valid  
797 calorimeter seed for a jet. To mitigate this confusion of multiple objects originating  
798 from a single jet or lepton overlapping objects are removed via a procedure referred  
799 to as overlap removal. In this procedure the separation of the two objects,  $\Delta(R) =$   
800  $\sqrt{(\Delta\eta)^2 + (\Delta\phi)^2}$  determines which object is removed from the event.

801 The overlap selections used in this analysis are:

- 802 - when an electron shares a track with another electron with the lower  $p_T$   
803 electron is rejected, as it is more likely to be a fake electron
- 804 - when a muon and electron share a track the muon is rejected if it is a  
805 calo-muon, otherwise the electron is rejected
- 806 - when  $\Delta R < 0.2$  for an electron and jet, the jet is rejected to maximize signal  
807 acceptance
- 808 - when  $\Delta R > 0.2$  for an electron and jet, the electron is rejected as likely  
809 originated from decays within the jet
- 810 - when  $\Delta R < \min(0.4, 0.04 + 10\text{GeV}/p_T^\mu)$  the muon is rejected, again maximiz-  
811 ing signal acceptance, otherwise the jet is rejected

<sub>812</sub>

- when  $\Delta R < 1.0$  for the a large-R jet and electron, the jet is rejected

813 **Chapter 7**

814 **Event Selection and**

815 **Categorization**

816 **7.1 Pre-selection**

817 Before applying topological cuts to suppress backgrounds and reduce data  
818 size in this search, preselection cuts are applied which include trigger and event  
819 requirements. Events must contain exactly one tight lepton (no additional loose  
820 leptons), the  $p_T^{\ell\nu} > 75$  GeV, and there must be at least two small-R jets or one  
821 large-R jet.

822 **7.2 Trigger**

823 The data were collected using the lowest unprescaled single-lepton or  $E_T^{miss}$   
824 triggers, as summarized in Table ???. Since the muon term is not considered in the  
825 trigger  $E_T^{miss}$  calculation, the  $E_T^{miss}$  trigger is fully efficient to events with high- $p_T$   
826 muons. For this reason, the  $E_T^{miss}$  trigger is used for events where  $p_T^\mu > 150$  GeV, to  
827 compensate for the poor efficiency of the single muon trigger above  $p_T^\mu > 150$  GeV.

**Table 7.1:** The list of triggers used in the analysis.

Data-taking period	$e\nu qq$ channel	$\mu\nu qq$ ( $p_T(\mu\nu) < 150$ GeV) channel	$\mu\nu qq$ ( $p_T(\mu\nu) > 150$ GeV) channel

828    **7.3 GGF/VBF RNN**

829    To classify events as originating from GGF/DY or VBF production a recursive  
830    neural network (RNN [17]) is used. This approach is more powerful than a cut-  
831    based classification as it improves signal efficiency and analysis sensitivity by  
832    exploiting correlations between variables that the RNN learns. In particular, a  
833    RNN architecture is ideal as it can handle variable numbers of jets in the events.

834    The RNN uses the four-momentum of candidate VBF jets to classify events  
835    as VBF or GGF topologies. As sometimes jets will be incorrectly reconstructed  
836    the number of jets in the event are expected to vary across the inputs samples.  
837    VBF candidate jets are identified by removing jets from the event that are likely  
838    from  $W/Z \rightarrow qq$ . For the resolved regime this means removing the two leading  
839    small-R jets from the VBF candidate jet list. For the merged regime this means  
840    removing small-R jets separated by less than 1.0 in  $dR$  from the large-R jet. VBF  
841    candidate jets are also required to be within  $|\eta| < 4.5$ . From the list of remaining  
842    VBF candidate jets, the two highest- $p_T$  jets are chosen.

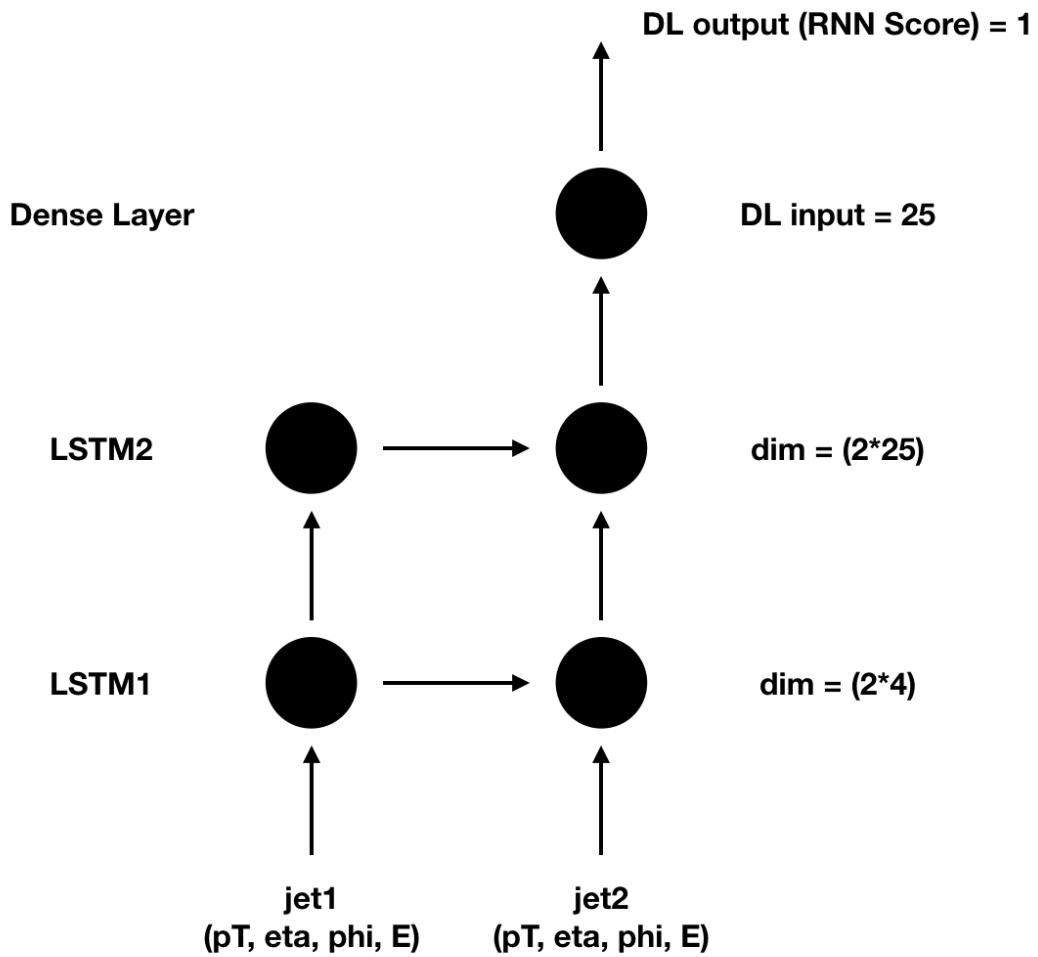

843    The architecture of the RNN is show in Figure 7.1. LSTMs are a type of  
844    RNN that extract meaningful information and can retain it (unlike other neural  
845    networks architectures). This is useful for VBF event classification for events with  
846    two jets, where using the kinematic properties of both jets (and their correlations)  
847    will lead to more efficient event classification.

848    In this RNN architecture, the VBF candidates are first passed to a masking  
849    layer which checks the number of jets in the event. If there is only one jet, only one  
850    LSTM layer is used. The output of masking is then passed to a Long Short-Term  
851    Memory (LSTM) cell, with a tanh activation function. This output is passed to  
852    a dropout layer, that has a probability of 0.3 to completely forget the output of  
853    the LSTM. Dropout is a regularization method, that prevents over-fitting. The

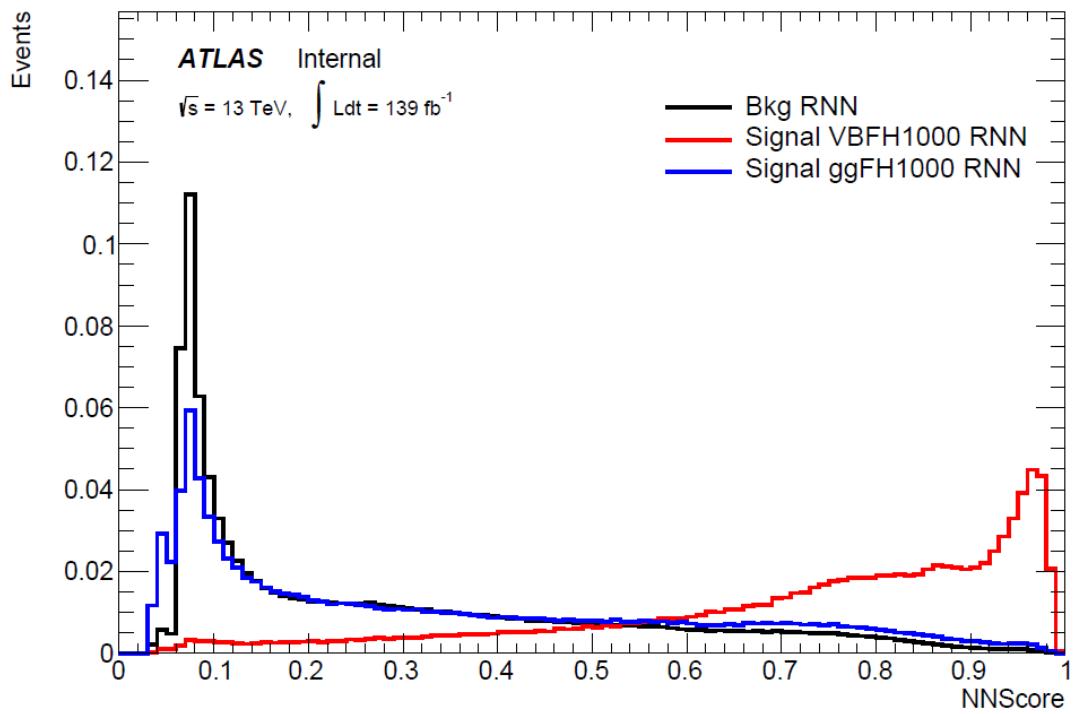

854 output of the dropout layer is then passed to the second LSTM and then through  
855 another dropout layer with a probability of 0.3.

856 The weights and other parameters of the network are learned by training the  
857 network with VBF and GGF signals over 200 epochs with an Adam Optimizer  
858 [natasha add reference]. The training is truncated if the network parameters are  
859 unchanged after ten iterations. The training, testing and validation sets are 56,  
860 30, and 14 percent of the input samples, respectively. Figure [add INT figure  
861 32] shows the loss function of the network as a function of training epochs. The  
862 validation test set has a smaller loss function as dropout was not applied. Figure  
863 7.3 shows the ROC curve for the RNN using k-fold cross validation.

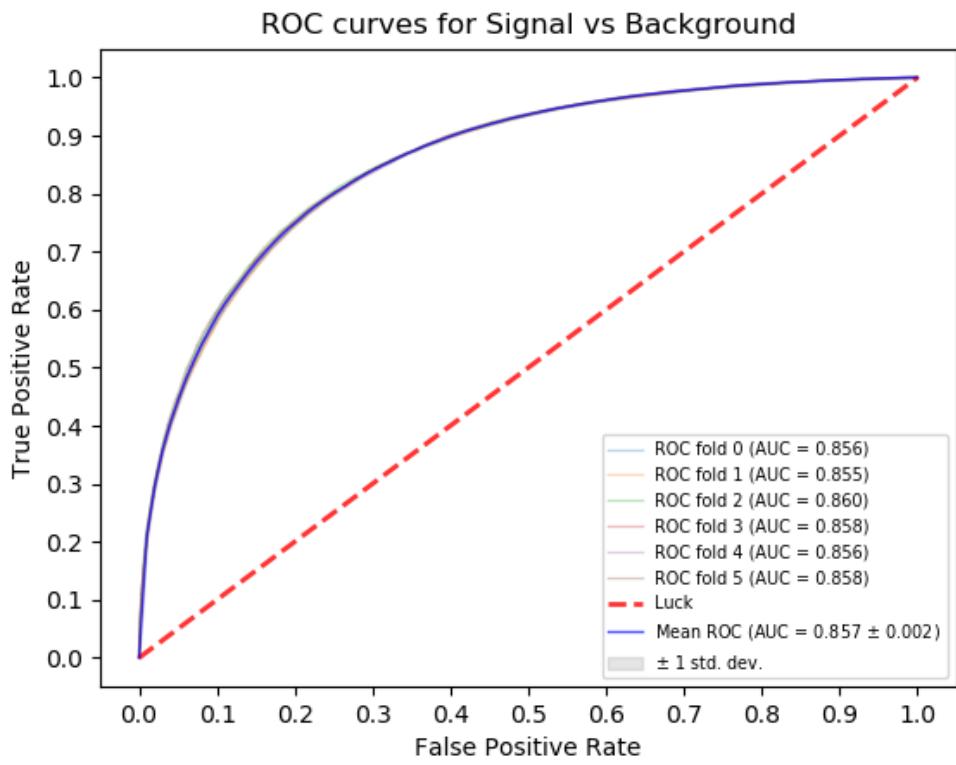

864 Finally this output is passed to a dense layer [natasha ask antonio about this]  
865 and then to a sigmoid activation layer, leading to an overall RNN score. Figure 7.2  
866 shows the RNN discriminant for backgrounds, GGF signals, and VBF signals. The  
867 RNN score is  $\sim 0$  for GGF and background processes and  $\sim 1$  for VBF processes.  
868 Figure 7.4 shows the limits for various signal processes based on the RNN cut  
869 applied. Requiring the RNN score to be  $> 0.8$  was chosen as it provided the best  
870 significance (and signal efficiency) across for this final state and the  $\nu\nu qq$  and  $\ell\ell qq$   
871 channels this channel will be combined with for future publications.

**Figure 7.3:** ROC curve using k-fold validation for RNN.

**Figure 7.4:** Comparison of GGF Z' limits for different RNN score selections. The bottom panel shows the ratio of the upper limits set for different RNN cuts to the cut-based analysis. In this panel smaller numbers, indicate that the expected upper limit is smaller than the cut-based analysis, which is desired.

## 872 7.4 Topological Cuts

873 Once an event is classified as VBF or GGF via the RNN it must pass other  
 874 topological cuts that maximize  $S/\sqrt{B}$ . First, to efficiently select events with  
 875  $W \rightarrow \ell\nu$  candidate exactly one tight lepton is required and  $E_T^{miss} > 100(60)$   
 876 GeV and  $p_{T,\ell\nu} > 200(75)$  GeV in the merged (resolved) analysis to suppress the  
 877 multi-jet background.

878 For the merged analysis, in addition to the  $W \rightarrow \ell\nu$  and  $W/Z \rightarrow J$  selections  
 879 above, the  $\min(p_{T,\ell\nu}, p_{T,J})/m_{WV} > 0.35(0.25)$  for the GGF (VBF) category. To  
 880 reduce  $t\bar{t}$  contamination events with the signal region and  $W+jets$  control region

881 events with at least one b jet with  $\Delta R > 1.0$  from the large-R jet are excluded.  
 882 High purity signal regions require the  $D_2$  and  $W/Z$  mass window cut to be passed,  
 883 whereas the low purity region only requires the  $W/Z$  mass window cut to be  
 884 passed. Finally for events to be classified as tagged the large-R jet must contain  
 885 exactly two b-tagged jets. Untagged events must have no more than one b-tagged  
 886 jet matched to the large-R jet. These selections are shown in Table 7.2. The  
 887 distributions for the variables used in merged analysis for top control regions are  
 888 shown in Figure 7.6-7.9.

889 Events failing the merged selection are then re-analyzed in the resolved cat-  
 890 egory. To enhance resolved signals, the event should contain two high- $p_T$  boson  
 891 candidates that are back-to-back in the  $\phi$  as shown by the cuts in Table 18. Again  
 892 to suppress the  $t\bar{t}$  background in the WCR and SR events are required to have no  
 893 additional b-jets.

894 The  $WV$  system mass,  $m_{WV}$  is reconstructed from the lepton, neutrino, and  
 895 hadronically-decaying boson candidate. The momentum of the neutrino along the  
 896  $z$ -direction is obtained by constraining the  $W$  boson mass of the lepton neutrino  
 897 system to be  $80.3 \text{ GeV}/c^2$ . For complex solutions to this constraint,  $p_Z$  is taken  
 898 as either the real component of the solution or the one with the smaller absolute  
 899 value of the two real solutions. For the resolved analysis,  $m_{WV}$  is reconstructed  
 900 by constraining the  $W(Z)$  dijet system:

$$p_{T,jj}^{corr} = p_{T,jj} \times \frac{m_{W/Z}}{m_{jj}} \quad (7.1)$$

$$m_{jj}^{corr} = m_{W/Z} \quad (7.2)$$

901 where  $m_{jj}$  and  $m_{W/Z}$  are the reconstructed invariant mass of the hadronically-  
 902 decaying  $W/Z$  boson and the PDG values of the  $W/Z$  boson masses, respectively.

**Table 7.2:** Summary of selection criteria used to define the signal region (SR),  $W$ +jets control region ( $W$  CR) and  $t\bar{t}$  control region ( $t\bar{t}$  CR) for merged 1-lepton channel.

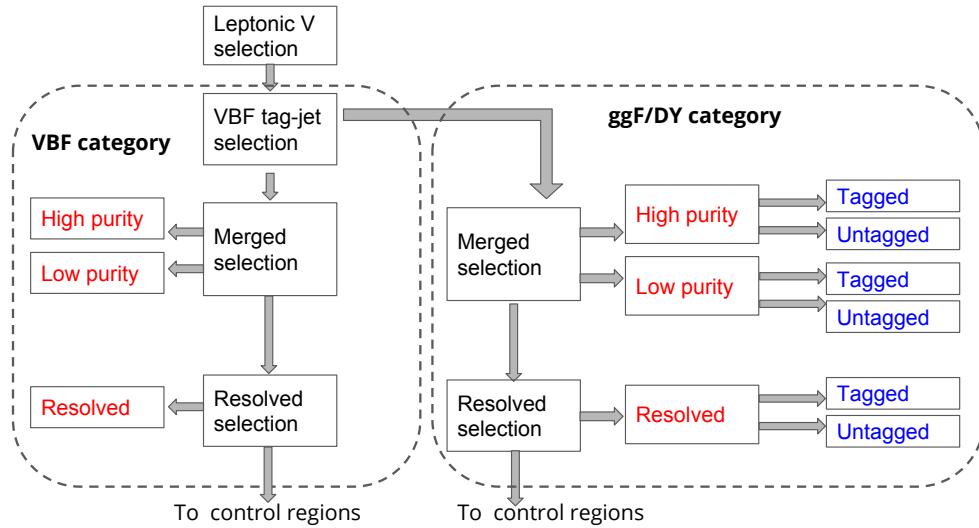

Selection		SR		W CR (WR)		$t\bar{t}$ CR (TR1)	
		HP	LP	HP	LP	HP	LP
$W \rightarrow \ell\nu$	Num of Tight leptons	1					
	Num of Loose leptons	0					
	$E_T^{\text{miss}}$	$> 100 \text{ GeV}$					
	$p_T(\ell\nu)$	$> 200 \text{ GeV}$					
$W/Z \rightarrow J$	Num of large- $R$ jets	$\geq 1$					
	$D_2$ cut	pass	fail	pass	fail	pass	fail
	$W/Z$ mass window cut	pass	pass	fail	fail	pass	pass
	Numb. of associated VR track jets $b$ -tagged	For $Z \rightarrow J$ : $\leq 1$ ( $= 2$ ) for untagged (tagged) category					
	$\min(p_{T,\ell\nu}, p_{T,J}) / m_{WV}$	$> 0.35(0.25)$ for DY/ggF (VBF) category					
	Top-quark veto	Num of $b$ -tagged jets outside of large- $R$ jet	0			$\geq 1$	
Pass VBF selection			no (yes) for DY/ggF (VBF) category				

904 A summary of the resolved selections is shown in Table 7.3. The distributions for  
905 the variables used in the resolved analysis in the TCR are shown in Figure 7.10,  
906 7.11.

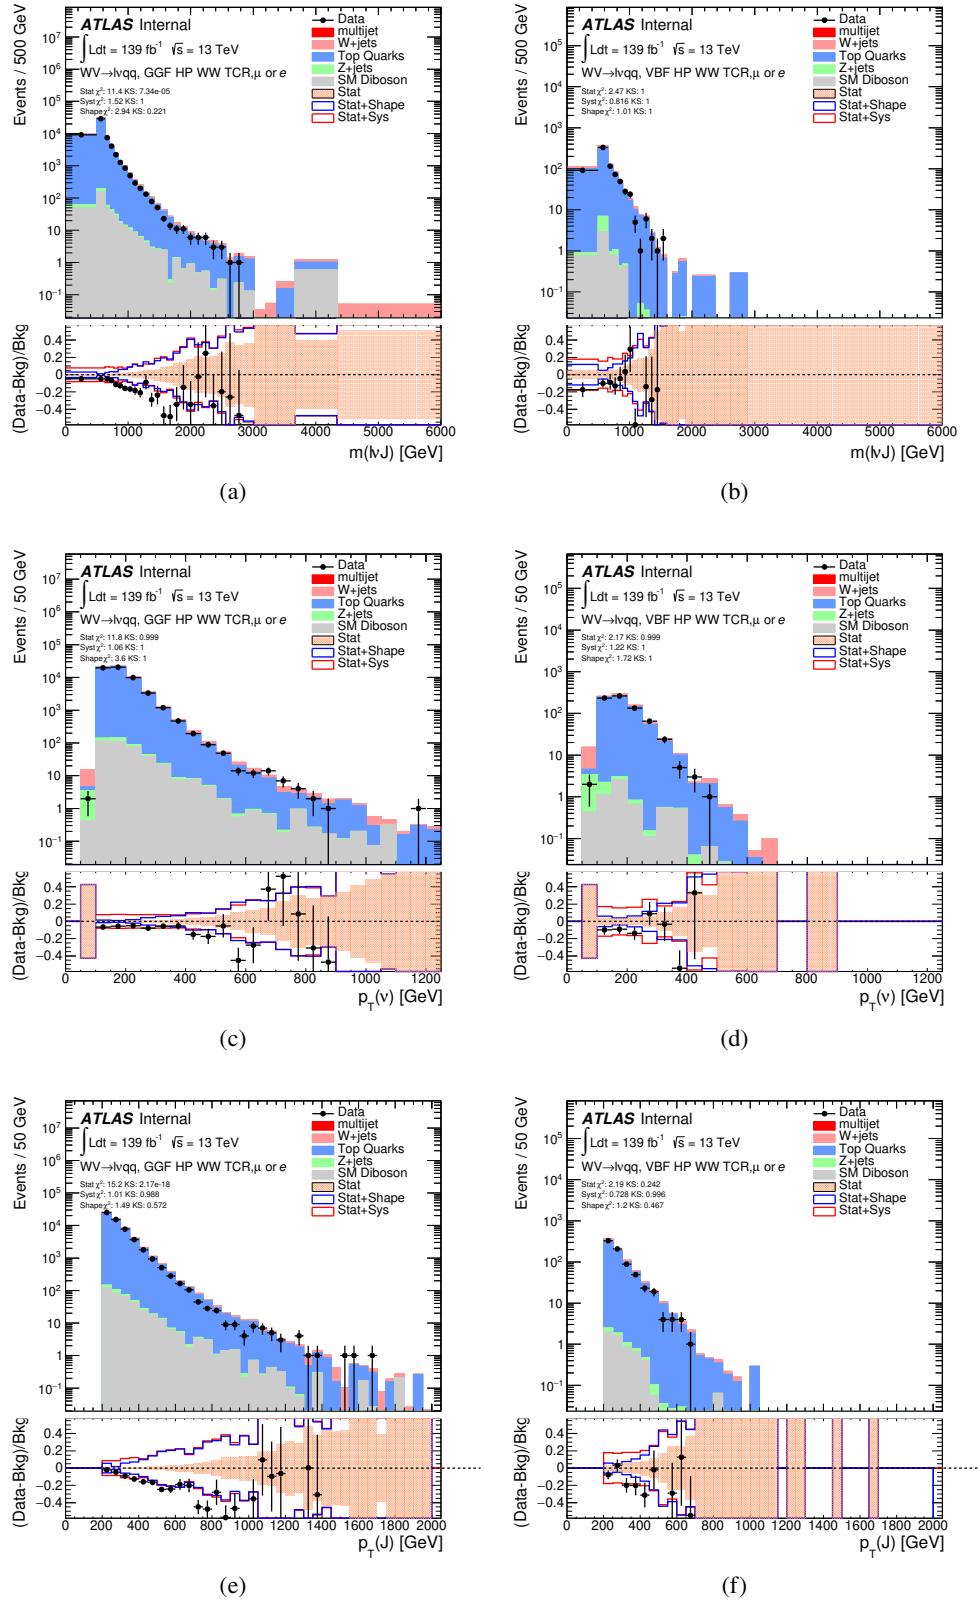

907 The analysis cutflow is shows in Figure 7.5. Events classified as VBF events  
908 are classified as Merged High purity, low purity or resolved signal region selections  
909 sequentially. If the event does not pass any of these selections but passes a VBF  
910 control region selection it is classified as a VBF CR event. If the event fails the  
911 VBF selection it is then checked if it passes the Merged High purity, Low purity  
912 or resolved signal region selections (NB: for the WZ decay modes all the region  
913 have tagged and untagged categories). If the event fails all the GGF signal region  
914 selections, it is then kept for GGF control region selections, if it passes those  
915 selections.

**Table 7.3:** The list of selection cuts in the resolved analysis for the  $WW$  and  $WZ$  signal regions (SR),  $W+\text{jets}$  control region (WR) and  $t\bar{t}$  control region (TR).

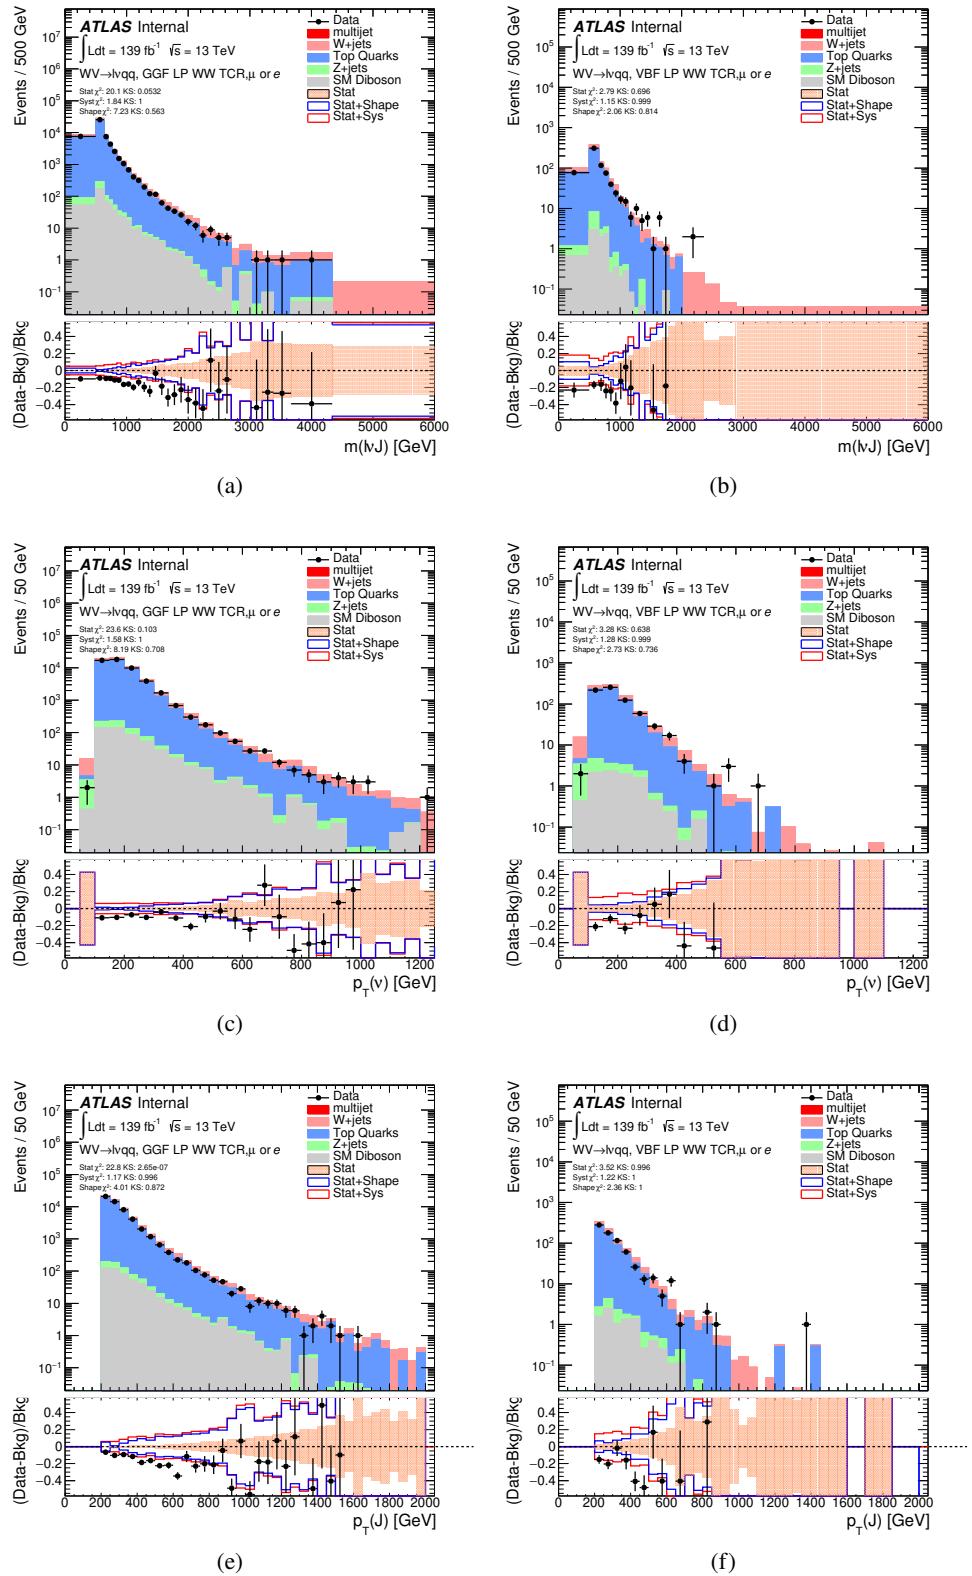

cuts	SR	$W$ CR (WR)	$t\bar{t}$ CR (TR1)
$W \rightarrow \ell\nu$	Number of Tight leptons	1	
	Number of Loose leptons	0	
	$E_T^{\text{miss}}$	$> 60 \text{ GeV}$	
	$\cancel{p}_T(\ell\nu)$	$> 75 \text{ GeV}$	
$W/Z \rightarrow jj$	Number of small-R jets	$\geq 2$	
	Leading jet $p_T$	$> 60 \text{ GeV}$	
	Subleading jet $p_T$	$> 45 \text{ GeV}$	
	$Z \rightarrow q\bar{q}$ $W \rightarrow q\bar{q}$	$78 < m_{jj} < 105 \text{ GeV}$ $68 < m_{jj} < 98 \text{ GeV}$	$50 < m_{jj} < 68 \text{ GeV}$ or $105 < m_{jj} < 150 \text{ GeV}$
Topology cuts	Num. of $b$ -tagged jets	For $Z \rightarrow jj$ : $\leq 1$ ( $= 2$ ) for untagged (tagged) category	
	$\Delta\phi(j, \ell)$	$> 1.0$	
	$\Delta\phi(j, E_T^{\text{miss}})$	$> 1.0$	
	$\Delta\phi(j, j)$	$< 1.5$	
	$\Delta\phi(\ell, E_T^{\text{miss}})$	$< 1.5$	
Topo veto	$\min(p_{T,\ell\nu}, p_{T,jj}) / m_{WW}$	$> 0.35(0.25)$ for DY/ggF (VBF) category	
	Number of additional $b$ -tagged jets	0	$\geq 1$
Pass VBF selection		no (yes) for DY/ggF (VBF) category

916    **7.5 Selection Acceptance times efficiency for Sig-**  
 917    **nal Events**

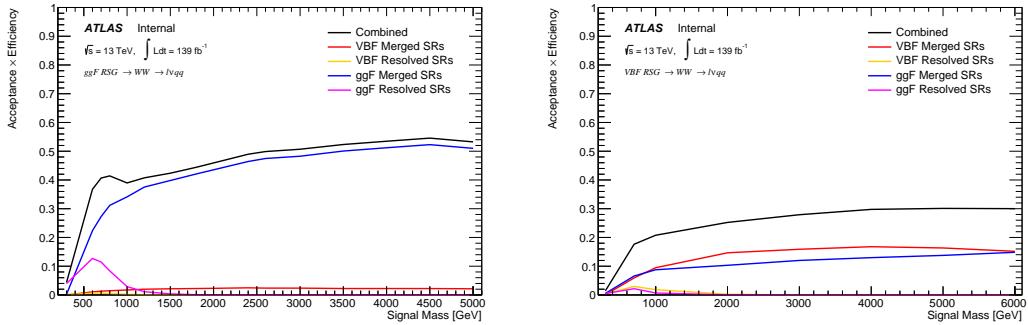

918    The acceptance times efficiency for the signal region selection is defined as:

$$A \cdot \epsilon = \frac{N_{\text{events selected}}^{\text{truth}}}{N_{\text{events generated}}^{\text{truth}}} \cdot \frac{N_{\text{events selected}}^{\text{reco}}}{N_{\text{events selected}}^{\text{truth}}} = \frac{N_{\text{events selected}}^{\text{reco}}}{N_{\text{events generated}}^{\text{truth}}} \quad (7.3)$$

919    The distributions of  $A \cdot \epsilon$  as a function of the resonance mass for the different spin  
 920    models are shown in Figures 7.13 - ??.

**Figure 7.12:** Selection acceptance times efficiency for the  $W' \rightarrow WZ \rightarrow \ell\nu qq$  events from MC simulations as a function of the  $W'$  mass for (a) Drell-Yan and (b) VBF production, combining the merged HP and LP signal regions of the  $WW \rightarrow \ell\nu J$  selection and the resolved regions of the  $WW \rightarrow \ell\nu jj$  selection.

**Figure 7.13:** Selection acceptance times efficiency for the  $G \rightarrow WW \rightarrow \ell\nu qq$  events from MC simulations as a function of the  $G$  mass for (a) Drell-Yan and (b) VBF production, combining the merged HP and LP signal regions of the  $WW \rightarrow \ell\nu J$  selection and the resolved regions of the  $WW \rightarrow \ell\nu jj$  selection.

## 921 7.6 Background Estimate

### 922 7.6.1 Control Regions

923 To more accurately model the two dominant backgrounds in this analysis,  
 924  $W+jets$  and  $t\bar{t}$ , control regions are used constructed for each. These control  
 925 regions are dominated by these processes and used to extract normalization factors  
 926 in the final likelihood fit that are then used in the signal region estimates. For  
 927 the  $t\bar{t}$  control region the event must contain at least one such b jet. The WCR is  
 928 constructed using the  $m_{jj/J}$  mass window sidebands. All other backgrounds are  
 929 estimated using simulation, except fake lepton backgrounds, which are derived  
 930 using a data-driven method.

### 931 7.6.2 Fake Lepton Backgrounds

932 Backgrounds in this analysis containing real leptons (e.g.  $W/Z+jets$ , diboson,  
 933  $t\bar{t}$ , single- $t$ ) are well-modeled with simulated samples and constrained with data  
 934 from CRs. However, the fake lepton background (also referred to as the multijet  
 935 background) is not well-modeled with simulation. For this reason, the multijet

background is extracted from data. Heavy flavor decay products, jets, and converted photons can be mistakenly reconstructed as electrons. Fake electrons often arise from jet fakes while non-prompt muons usually arise from heavy flavor decay. For this analysis, these fake electrons generally fail the electron ID criteria and fake muons fail the muon isolation requirement. Therefore, to derive the multijet template shape the SR and CR selections and inverted lepton requirements are used as seen in Table 7.4. NB: by inverting the lepton isolation/identification criteria the SRs and CRs are orthogonal.

The template shape of the MJ background is determined by using a multijet validation region (MJVR) that requires the inverted lepton isolation/identification requirement and the two signal jets to satisfy the  $m_{jj}$  requirement used in the  $W+jets$  CRs. The  $E_T^{miss}$  distribution in MJCR is shown in Figure 7.14 for 2017 data. The template is then extracted by subtracting the data in the MJVR from the electroweak background processes. The resulting template and electroweak backgrounds are then fit to data. In this fit, the  $E_T^{miss}$  distribution compared to data to extract electroweak background, multijet electron and muon background normalizations. The fitted scale factors from this MJVR template are then applied in the MJCR template. The electron and muon background normalizations in the MJCR template are parameters in the final simultaneous fit. Technically, there should be a separate template for every CR and SR, but some MJ regions have insufficient statistics to do this. Additionally, the shapes for the MJ templates for VBF and ggF regions are found to be compatible within statistical uncertainty. Therefore, the sample MJ template used for VBF and ggF CR/SRs, but with different pre-MJ-fit scale factors.

This template method was validated using WCR and full Run 2 data. The results of the fit are shown in Table 7.5. The multijet contribution in the muon

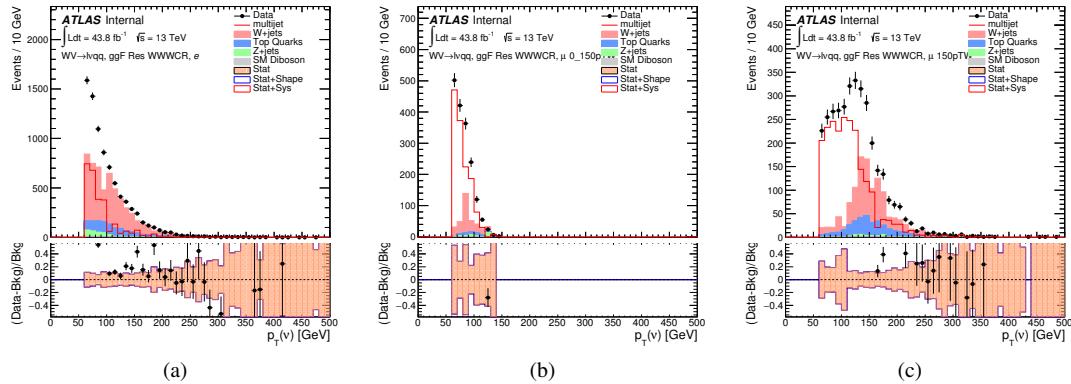

962 channel for  $p_T^W > 150$  GeV is consistent with zero, and therefore neglected in  
 963 the final fit. Applying the extracted normalization factor to MJVR in WCRs for  
 964 various kinematic variables such as  $E_T^{miss}$ ,  $W$  transverse mass, lepton  $p_T$ , and the  
 965 invariant mass as show in Figures 7.15 -7.24. These figures show good agreement  
 966 between the data and background estimate.

**Table 7.5:** Fit validation result in WCRs for 2015+16 data. The fit is done in various WCRs, in order to obtain the corresponding scale factors for MJ templates: ggF resolved WCR for the  $WW \rightarrow lvqq$  selection, ggF resolved untagged WCR for the  $WZ \rightarrow lvqq$  selection, ggF resolved tagged WCR for the  $WZ \rightarrow lvqq$  selection, VBF resolved WCR for the  $WW \rightarrow lvqq$  selection, and VBF resolved WCR for the  $WZ \rightarrow lvqq$  selection. Post-fit event yields for electroweak processes and MJ contributions are shown. The SF column shows the corresponding normalization scale factors for electroweak processes from the fit. R.U. stands for relative uncertainty.

968 **Chapter 8**

969 **Systematic Uncertainties**

970 This section describes the sources of systematic uncertainties considered in  
971 this analysis. These uncertainties are divided into three categories: experimental  
972 uncertainties, background modeling uncertainties, and theoretical uncertainties on  
973 signal processes. In the statistical analysis each systematic uncertainty is treated  
974 as a nuisance parameter estimated on the  $m_{VV}$  distribution.

975 **8.1 Experimental Systematics**

976 The uncertainty on the integrated luminosity of the dataset used is 1.7% and  
977 a systematic in the final fit. The luminosity uncertainty is calculated following a  
978 methodology similar to the one in [ref P55].

979 Also, multiple pile up interactions are simulated to match data conditions.  
980 This ensures simulated detector response and particle reconstruction conditions  
981 are as similar as possible. The distribution of the average number of interactions  
982 per bunch crossing applied to simulation is called the  $\mu$  profile. The pileup mod-  
983 eling uncertainty is accounted for by re-weighting simulated events so the average  
984 number of interactions per bunch crossing varies within its uncertainty due to

985 systematics from vertex reconstruction [ref ATL-COM-SOFT-2015-119]. The as-  
986 sociated re-weighting factors are propagated through the entire analysis chain to  
987 construct a systematic uncertainty on  $m_{VV}$ .

988 The single-lepton and  $E_T^{miss}$  triggers used are not fully efficient and therefore  
989 simulated data must be scaled to account for trigger inefficiencies. Trigger effi-  
990 ciencies are given by the ratio of the distribution of offline objects before trigger  
991 selection and after trigger selection.

992 Uncertainties on small-R jet energy scale and resolution are measured in-situ  
993 by calculating the response between data and simulation. This analysis uses a  
994 reduced set of JES and JER uncertainties (totaling 30 and 8 systematics, re-  
995 spectively). These reduced sets of systematics are calculated using a principal  
996 component analysis, yield largely uncorrelated independent systematics. These  
997 uncertainties account for the dependence on  $p_T$ ,  $\eta$ ,  $\mu$ , flavor response and global  
998 sequential corrections. Systematic uncertainties associated with  $b$ -tagging are also  
999 considered. These systematics are evaluated as uncertainties on the scale factor  
1000 which account for the difference in  $b$ -tagging efficiencies in data and MC, and the  
1001 flavor dependence (between b, c, and light jets).

1002 The uncertainty on the  $p_T$  scale of the large-R jets is determined by comparing  
1003 the jet's  $p_T^{calo}$  to  $p_T^{track}$  in di-jet simulation and data. In addition to this uncertain-  
1004 ties from tracking, modeling (Pythia vs Herwig), and statistical constraints are  
1005 also calculated. The large-R jet  $p_T$  resolution is given by smearing the jet  $p_T$  with  
1006 a Gaussian with a 2% width.

1007 The  $W/Z$ -tagging efficiency cannot be evaluated using the Rtrk method as the  
1008 TCC algorithm uses track measurements to reconstruct jet substructure variables.  
1009 In order to avoid this potential bias, the  $W/Z$ -tagging estimated in data using a  
1010 control sample and correct by comparing it with simulation. The efficiency to

1011     $W/Z$ -induced signal is estimated by a  $t\bar{t}$  control sample, while the efficiency to  
1012    single- $q/g$  background is estimated using a dijet sample. The effects of experimen-  
1013    tal and theoretical uncertainties on the efficiency scale factor are by taking the  
1014    ratio of efficiencies in data and simulation. By taking this ratio the uncertainties  
1015    not arising for jet mass and  $D_2$  cancel.

1016       Lepton identification, reconstruction, isolation systematic uncertainties are de-  
1017    termined by reconstructing the Z mass peak with a tag and probe method. The  
1018    lepton energy and momentum scales are also measured with the Z mass peak.  
1019    Additionally, the track-to-vertex association efficiency is used for muons.

1020       As  $E_T^{miss}$  is calculated using all the physics objects in the event, all those objects  
1021    associated errors result in an uncertainty on  $E_T^{miss}$ . Additionally, the unassociated  
1022    tracks used to construct  $E_T^{miss}$  contribute to the uncertainty on  $E_T^{miss}$ .

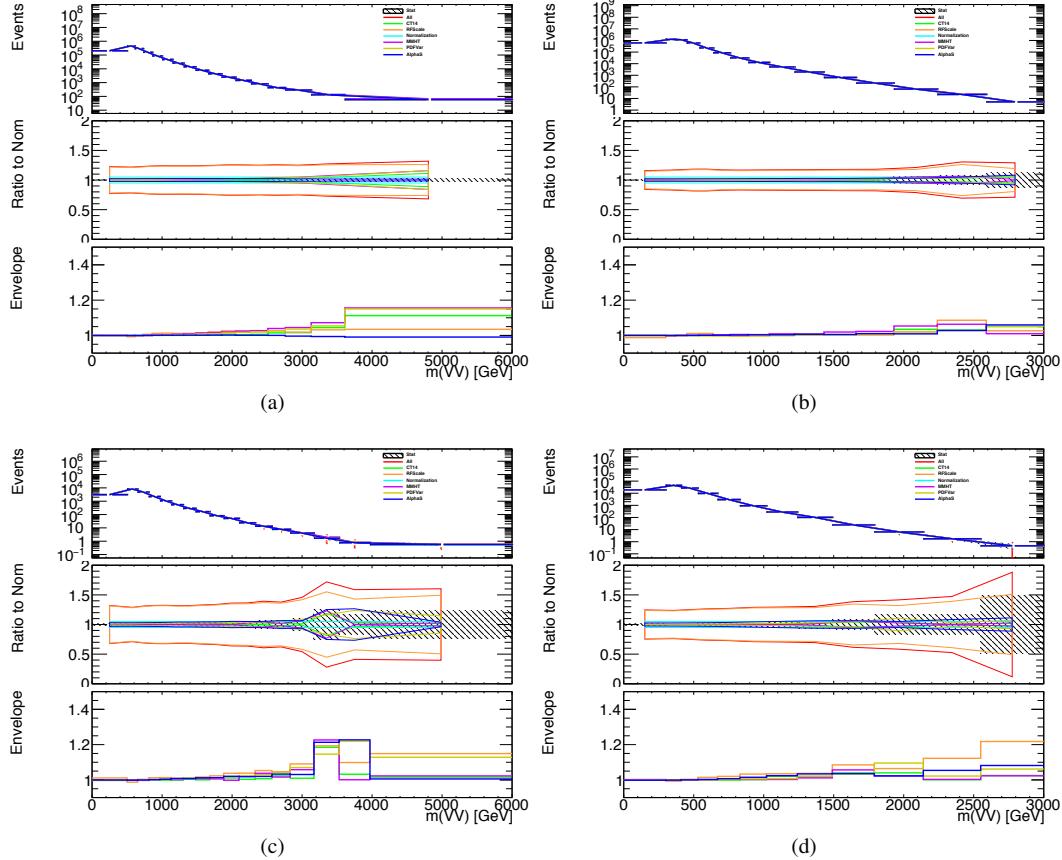

## 1023    8.2 Theory Systematics

1024       Theoretical uncertainties for signal and background processes arise from un-  
1025    certainties in the parameters used in Monte Carlo simulation. In particular for  
1026    the  $t\bar{t}$ ,  $W/Z+jets$ , and diboson backgrounds and signal samples the QCD scale,  
1027    PDF, generator and hadronization uncertainties were evaluated. To assess the  
1028    QCD scale uncertainty the renormalization and factorization scales were scaled  
1029    up (2.0) and down (0.5) at the event generation stage of sample production. Un-  
1030    certainties due to the choice of the parton distribution functions were evaluated  
1031    by re-weighting samples from the nominal PDF to a set of error PDFs which ac-  
1032    count for the uncertainty of the fits used to produce the PDF set. In addition to  
1033    this samples are re-weighted to different PDF sets to account for the arbitrariness  
1034    of the PDF choice. The difference between the  $m_{WV}$  distributions using differ-  
1035    ent event generators is assessed by comparing samples generated with different

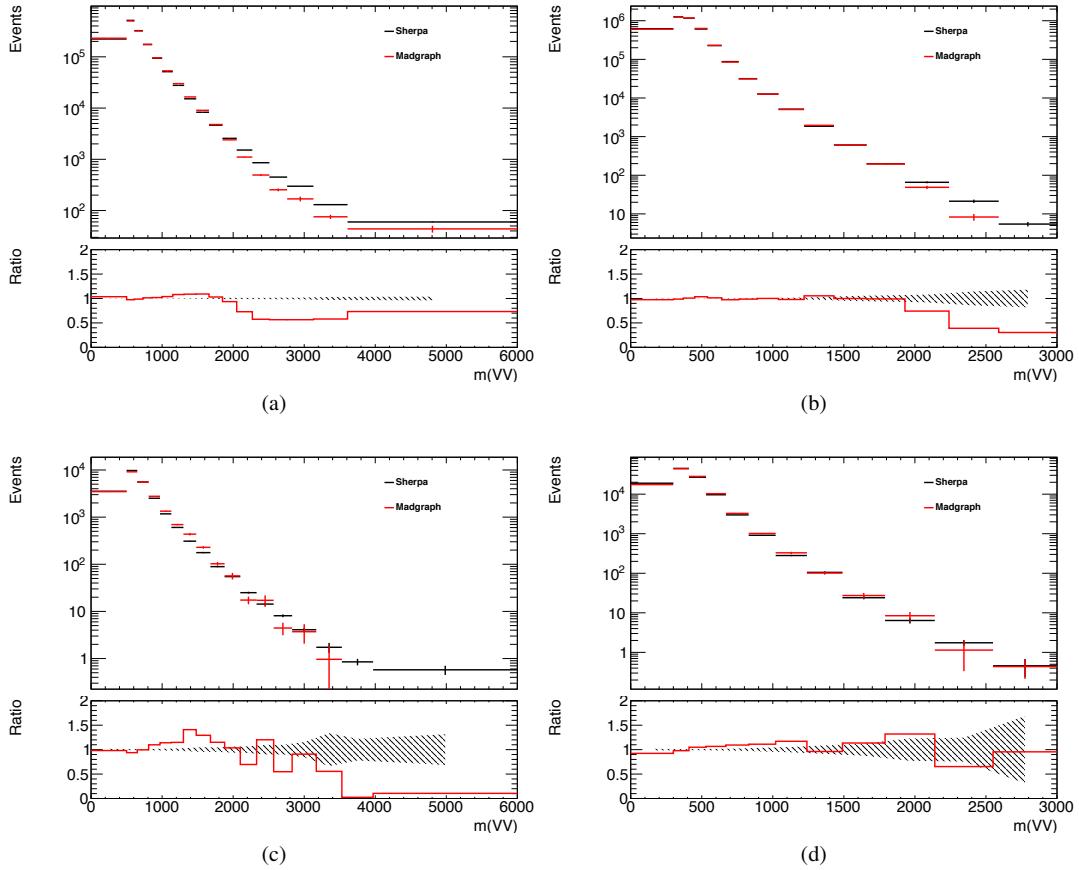

1036 generators. Similarly, the uncertainty in hadronization models is account for by  
1037 comparing samples created using different hadronization models (e.g. Pythia8 vs.  
1038 Herwig7). Figures 8.2 - 8.8 show the impact of these uncertainties on the  $t\bar{t}$  and  
1039  $W/Z + \text{jets}$  backgrounds.

1040 Additionally, contributions to the diboson background for the VBF analysis  
1041 were included in [SOME WAY that is not determined yet].

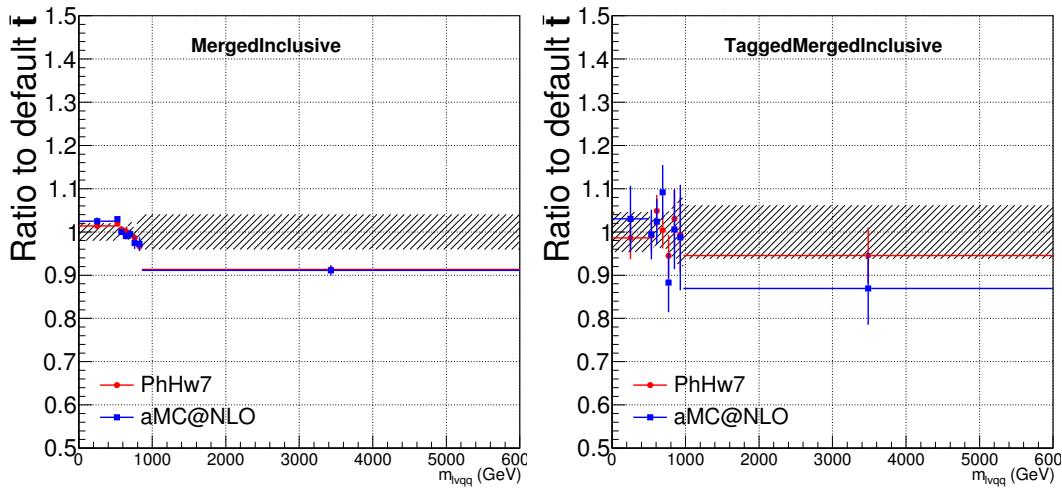

1042 The normalization of the  $t\bar{t}$  and  $W+\text{jets}$  processes impact the multijet template  
1043 shape. The impact of these normalization is assess by including a shape systematic  
1044 on the multijet background from varying the  $t\bar{t}$  and  $W+\text{jets}$  normalization factors.

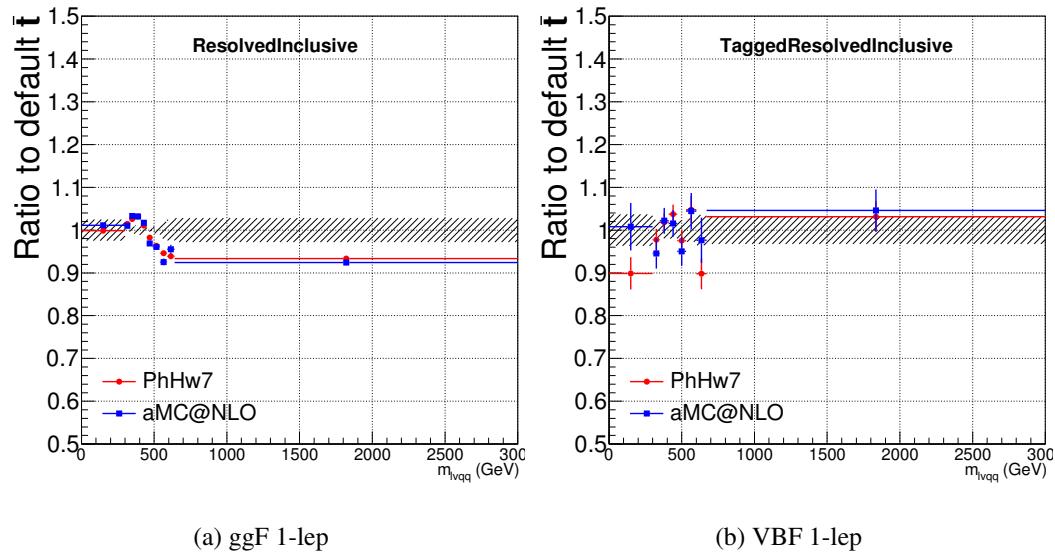

**Figure 8.1:** The  $W/Z + \text{jet}$  systematics for the a) Merged ggF, b) Resolved ggF, c) Merged VBF, and d) Resolved VBF regions. The top subplot shows the nominal and variation distributions/bands, the middle shows the ratio of the two, and the final shows just the shape of the envelope (the final uncertainty).

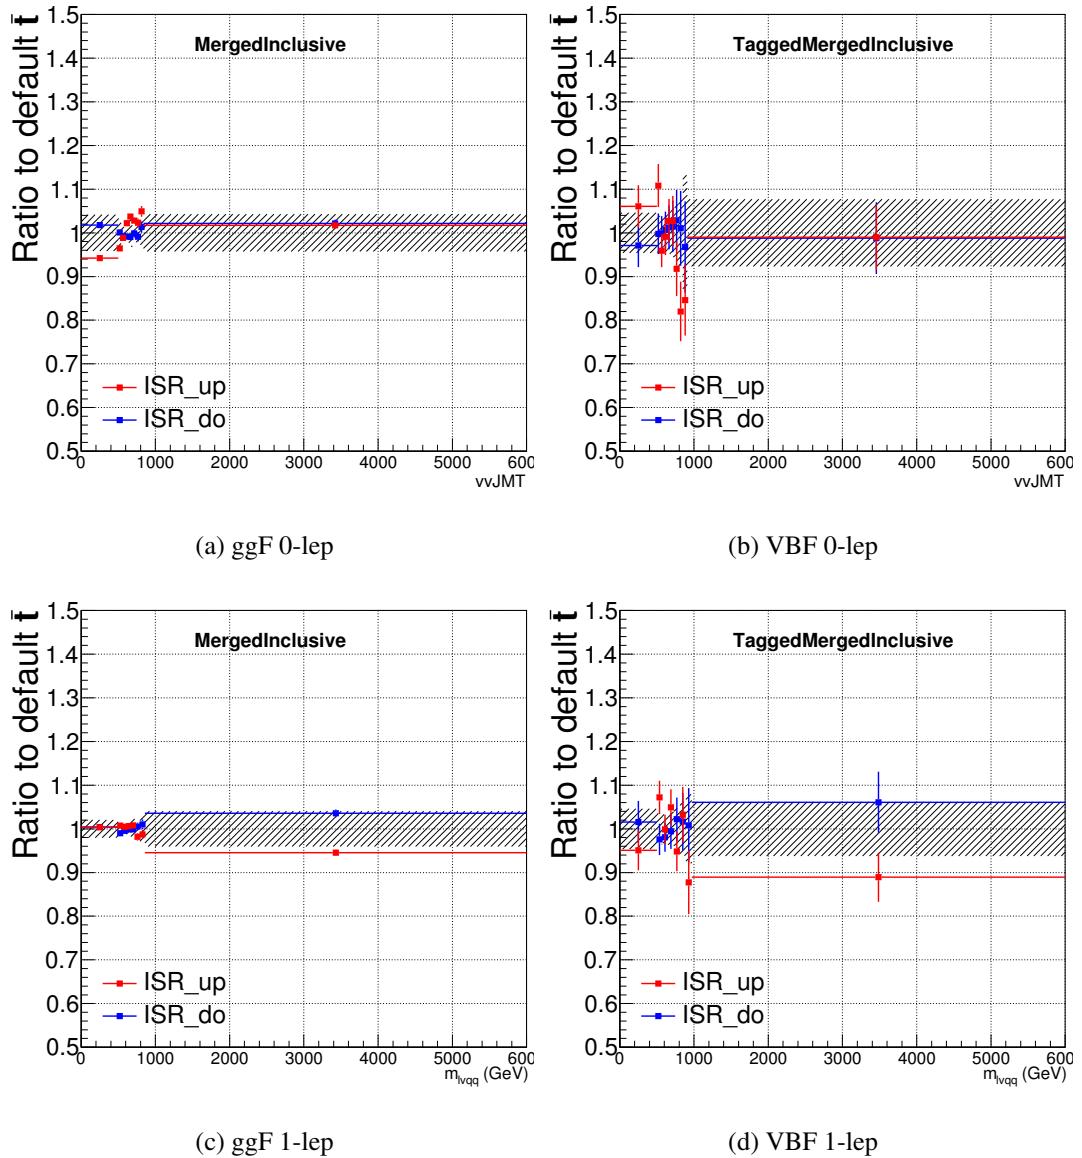

**Figure 8.2:** The two-point generator comparison between Sherpa and MadGraph for the  $W/Z + \text{jet}$  samples in the a) Merged ggF, b) Resolved ggF, c) Merged VBF, and d) Resolved VBF regions. The normalization of the Madgraph sample is set to the Sherpa value to consider only shape effects. The bottom inset shows the ratio of the two.

1045 **Chapter 9**

1046 **Statistical Analysis**

1047 To determine the compatibility of the data collected with the proposed reso-  
1048 nances a statistical procedure based on a likelihood function is used. A discovery  
1049 test is used to measure the compatibility of the observed data with the back-  
1050 ground only hypothesis. If the observed data is sufficiently incompatible with the  
1051 background only hypothesis, this could indicate a discovery. In the absence of  
1052 discovery, upper limits on the signal strength parameter,  $\mu$ , are assessed using the  
1053 CLs method.

1054 **9.1 Likelihood Function Definition**

1055 The likelihood function is product of Poisson probabilities for all analysis bins  
1056 and systematic constraints:

$$\mathcal{L}(\mu, \boldsymbol{\theta}) = \prod_c \prod_i \frac{(\mu s_{ci}(\boldsymbol{\theta}) + b_{ci}(\boldsymbol{\theta}))^{n_{ci}}}{n_{ci}!} e^{-(\mu s_{ci}(\boldsymbol{\theta}) + b_{ci}(\boldsymbol{\theta}))} \prod_k (\theta'_k | \theta_k) \quad (9.1)$$

1057 Here  $c$  are the analysis channels considered and  $i$  runs over all the  $m_{\ell\nu qq}$  bins  
1058 used in the fit. The signal strength parameter,  $\mu$ , multiplies the expected signal

yield in each analysis bin,  $s_{ci}$ . The background content for channel  $c$  and bin  $i$  is given by  $b_{ci}$ . The dependence of signal and background predictions on systematic uncertainties is described by the aforementioned set of nuisance parameters  $\boldsymbol{\theta}$ , which are parameterized by Gaussian or log-normal priors denoted here as  $\theta_k$ . Statistical uncertainties of the simulated bin contents are also included as systematic uncertainties. Most systematics are correlated among all the analysis regions and considered to be independent from each other. The validity of this assumption is checked by evaluating the covariance of nuisance parameters.

## 9.2 Fit Configuration

The binning of  $m_{\ell\nu qq}$  in signal regions for likelihood fit is determined by the statistical uncertainty of signal mass width. For each signal mass point, the signal mass resolution is given by the fitted Gaussian width of the  $m_{\ell\nu qq}$ . The fitted signal widths are then fit to a line to give a parameterized signal mass width, as shown in Figures 9.1 and 9.2. Bin widths are set first to this parameterized signal mass resolution. Then if the statistical uncertainty of the data or simulated background is more than 50%, bins are merged until the statistical uncertainty is less than 50%. All control regions contain only a single bin.

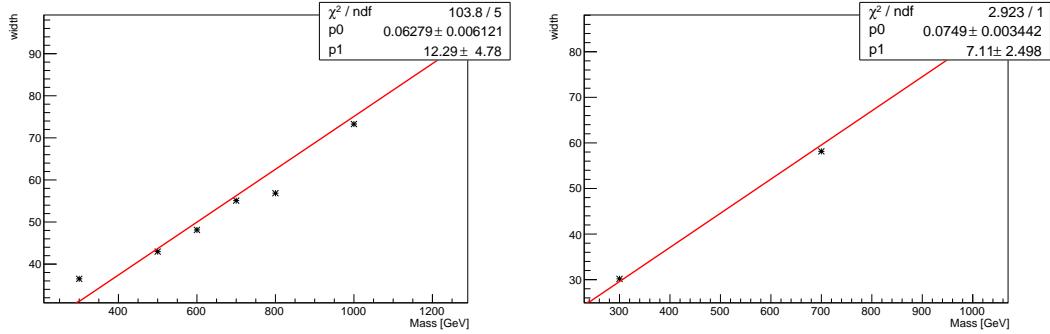

For this analysis, each signal model fits the Merged and Resolved channels for the relevant signal production mode simultaneously. The control regions are used to extract  $W + \text{jets}$  and  $t\bar{t}$  backgrounds normalizations in the signal regions.

Systematics may be affected by low statistics, leading to unsmooth  $m_{VV}$  distributions with unphysically large fluctuations. This can lead to artificial pulls and constraints in the fit. To remove such issues a multi-step smoothing procedure is applied to all systematic variation distributions in all regions. First, distributions are rebinned until the statistical error per bin is at least 5%. Next

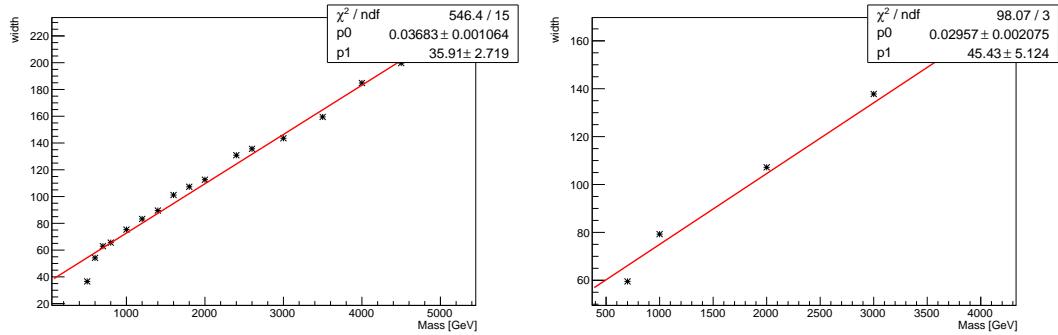

1084 all local extrema are identified. The bins around smallest extrema are iteratively  
1085 merged until only four local extrema remain. Then distributions are rebinned so  
1086 that statistical uncertainties in each bin are  $< 5\%$ .

1087 For some systematics, up and down variations may be in the same direction  
1088 with respect to the nominal distributions, leading to asymmetric distributions.  
1089 This causes the variations to not cover the nominal choice, and the interpretation  
1090 of the confidence interval is skewed. This asymmetry may also lead to uncon-  
1091 strained systematics in the fit. To handle such asymmetric systematics, if the up  
1092 and down variation for a given systematic are in the same direction for at least  
1093 three  $m_{VV}$  bins the variation is averaged for those bins. The averaging proce-  
1094 dure replaces bin-by-bin the up and down variation bins by  $b_{\pm}^{new} = b_{nom} \pm \frac{|b_+ - b_-|}{2}$ ,  
1095 where  $b_{nom}$  is the nominal bin content and  $b_{\pm}$  are the original up and down varia-  
1096 tion bin content. The same procedure is also applied to any variations where the  
1097 integral of the difference between the up/down variation and the nominal distri-  
1098 bution is twice that of the other down/up variation, further ensuring variations  
1099 are symmetric around the nominal distribution.

1100 Finally, systematics that have a negligible effect on the  $m_{VV}$  distribution are  
1101 not considered in the fit. Shape systematics where no bin in the variational dis-  
1102 tribution deviates more than 1% from the nominal distribution (after normalizing  
1103 all histograms to the nominal) are not included in the fit. Also, statistical bin  
1104 uncertainties  $< 1\%$  are ignored.

**Figure 9.1:** The HVT signal mass resolution as a function of mass fit with a straight line in the Resolved ggF region (left) and VBF (right) region.

**Figure 9.2:** The HVT signal mass resolution as a function of mass fit with a straight line in the Merged ggF region (left) and VBF (right) region.

### 1105 9.3 Best Fit $\mu$

1106     The best fit signal strength parameter is denoted by  $\hat{\mu}$  and calculated by  
 1107     maximizing the likelihood function with respect to all systematics and  $\mu$ . The  
 1108     corresponding set of systematics that maximize the likelihood are given by  $\hat{\mu}$ .  
 1109     The first term in the likelihood is maximized when the expected number of signal  
 1110     and background events is equal to the number of events in data ( $n_{ci} = \mu s_{ci} +$   
 1111      $b_{ci}$ ). Thus, by maximizing the likelihood, the fit determines values of  $\mu$  and  $\theta$   
 1112     that give the best agreement between expected and measured event yields. The

1113 second term in the likelihood is a penalty term which decreases the likelihood  
1114 when systematics are shifted from their nominal values. This prevents the fit  
1115 from profiling systematics in unphysical ways to maximize the likelihood. The  
1116 uncertainty on  $\mu$  is calculated by varying  $\mu$  up and down until the natural log of  
1117 the likelihood function shifts by one-half.

## 1118 9.4 Discovery Test

1119 To determine if the observed dataset is consistent with tested signal model a  
1120 likelihood ratio is constructed:

$$\lambda(\mu) = \frac{\mathcal{L}(\mu, \hat{\theta}_\mu)}{\mathcal{L}(\hat{\mu}, \hat{\theta})} \quad (9.2)$$

1121 The denominator in this equation is the maximized value of  $\mathcal{L}$  over all system-  
1122 atics and  $\mu$ . The numerator is the maximized likelihood over all systematics for  
1123 a given  $\mu$  value, where the maximized systematics are given by  $\hat{\mu}_\mu$ . To test for  
1124 the existence of signal the observed dataset the null hypothesis ( $H_0$ ) is defined as  
1125 the background only hypothesis and the alternate hypothesis includes signal and  
1126 background ( $H_1$ ). This test quantifies the compatibility of observed data with  
1127  $H_0$  by calculating a p-value representing the probability of observing data as dis-  
1128 crepant or more than the observed data under the  $H_0$ . The test statistic used to  
1129 calculate this p-value is given by ( $r_0$ ):

$$r_0 = \begin{cases} -2 \ln \lambda(0), \hat{\mu} > 0 \\ +2 \ln \lambda(0), \hat{\mu} < 0 \end{cases} \quad (9.3)$$

1130 The expected distribution of the the test statistic under  $H_0$  ( $f(r_0|0)$ ) is used to  
1131 calculate the p-value:

$$p_0 = \int_{r_0, obs}^{\infty} f(r_0 | 0) dr_0 \quad (9.4)$$

1132        Small p-values indicate the observed data is poorly described by  $H_0$ . This  
 1133        equivalent Z-score of a given p-value is usually used to further quantify the agree-  
 1134        ment between the observed data and  $H_0$ . The Z-score is given by the number of  
 1135        standard deviations away from the mean of a Gaussian distribution, the integral  
 1136        of the upper tail of the distribution would equal the p-value. Mathematically:

$$Z = \Phi^{-1}(1 - p_0) \quad (9.5)$$

1137        where  $\Phi$  is the Gaussian cumulative distribution function. The statistical  
 1138        significance of these tests are expressed as the  $Z$ -score. In particle physics,  $3\sigma$  is  
 1139        considered evidence for new phenomena and  $5\sigma$  is the threshold for discovery.

## 1140        9.5 Exclusion Limits

1141        In the absence of discovery, upper limits on the signal strength,  $\mu$  are set using  
 1142        the CLs method [cite P60]. The test statistic for this test,  $q_\mu$ , is constructed as:

$$\tilde{\lambda}_\mu = \begin{cases} \frac{\mathcal{L}(\mu, \hat{\theta}_\mu)}{\mathcal{L}(\hat{\mu}, \hat{\theta})}, \hat{\mu} > 0 \\ \frac{\mathcal{L}(\mu, \hat{\theta}_\mu)}{\mathcal{L}(0, \hat{\theta}_0)}, \hat{\mu} < 0 \end{cases} \quad (9.6)$$

$$\tilde{q}_\mu = \begin{cases} -2 \ln \tilde{\lambda}(\mu), \hat{\mu} < \mu \\ +2 \ln \tilde{\lambda}(\mu), \hat{\mu} > \mu \end{cases} \quad (9.7)$$

1143        As defined, larger values of  $q_\mu$  correspond to increasing incompatibility between  
 1144        the observed data and the background + signal hypothesis. The observed value  
 1145        of the test statistic,  $q_{\mu, obs}$ , is then compared to its expected distribution,  $f$ , to

1146 calculate p-values to assess the likelihood of the background+signal hypothesis.

1147 Using these distributions,  $CL_s$  values are computed as:

$$CL_{s+b} = \int_{q_{\mu,obs}}^{\infty} f(q_{\mu}|\mu) dq_{\mu} \quad (9.8)$$

1148

$$CL_b = \int_{q_0^{obs}}^{\infty} f(q_{\mu}|\mu = 0) dq_{\mu} \quad (9.9)$$

1149

$$CL_s = \frac{CL_{s+b}}{CL_b} \quad (9.10)$$

1150  $CL_{s+b}$  is the p-value for the signal + background hypothesis and  $CL_b$  is the  
1151 p-value for the background only hypothesis. The  $CL_s$  value is interpreted as  
1152 the probability to observe the background + signal hypothesis normalized to the  
1153 probability of background-only hypothesis. Normalizing by  $CL_b$  prevents setting  
1154 artificially strong exclusion limits due to downward fluctuations in data.

1155 In this analysis,  $\mu$  values are scanned for each bin in the fit to find the  $\mu$  value  
1156 that yields  $CL_s=0.05$ , meaning the likelihood of finding data more incompatible  
1157 with the signal+background hypothesis (relative to the background only hypothesis)  
1158 is 5%. The 95% upper limit on the cross section is then calculated as the  
1159 product of the  $\mu$  value found, branching ratio, and theory cross section.

## Part IV

<sup>1161</sup>

## Results

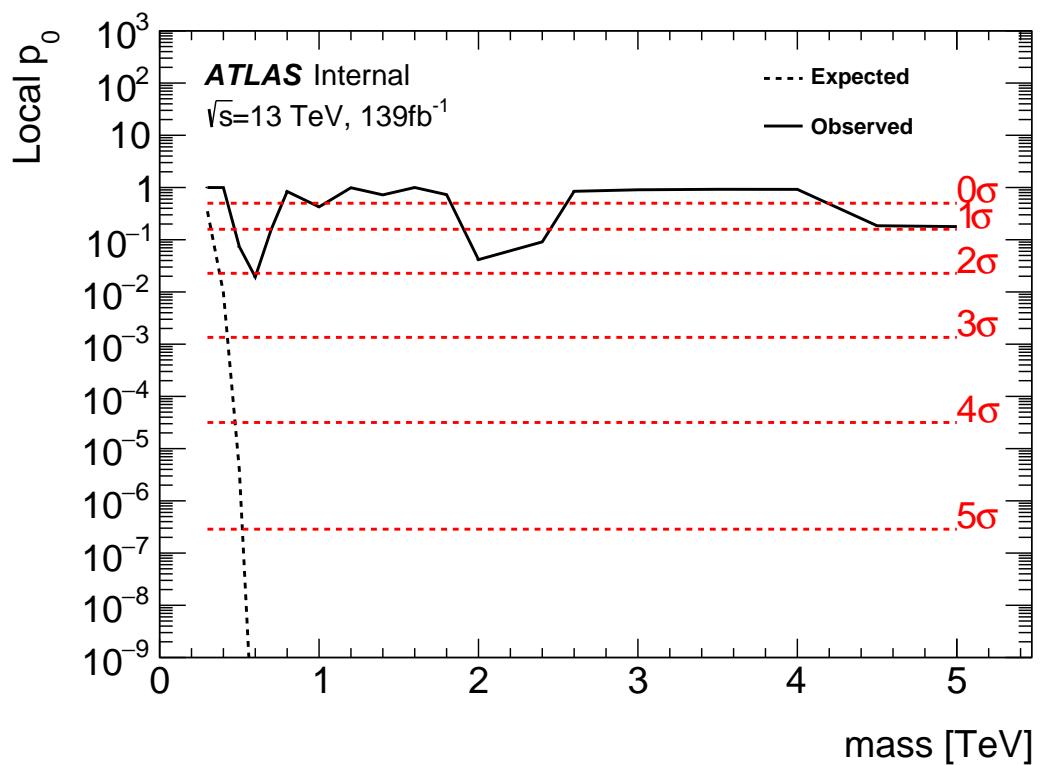

<sup>120</sup>

1162 **Chapter 10**

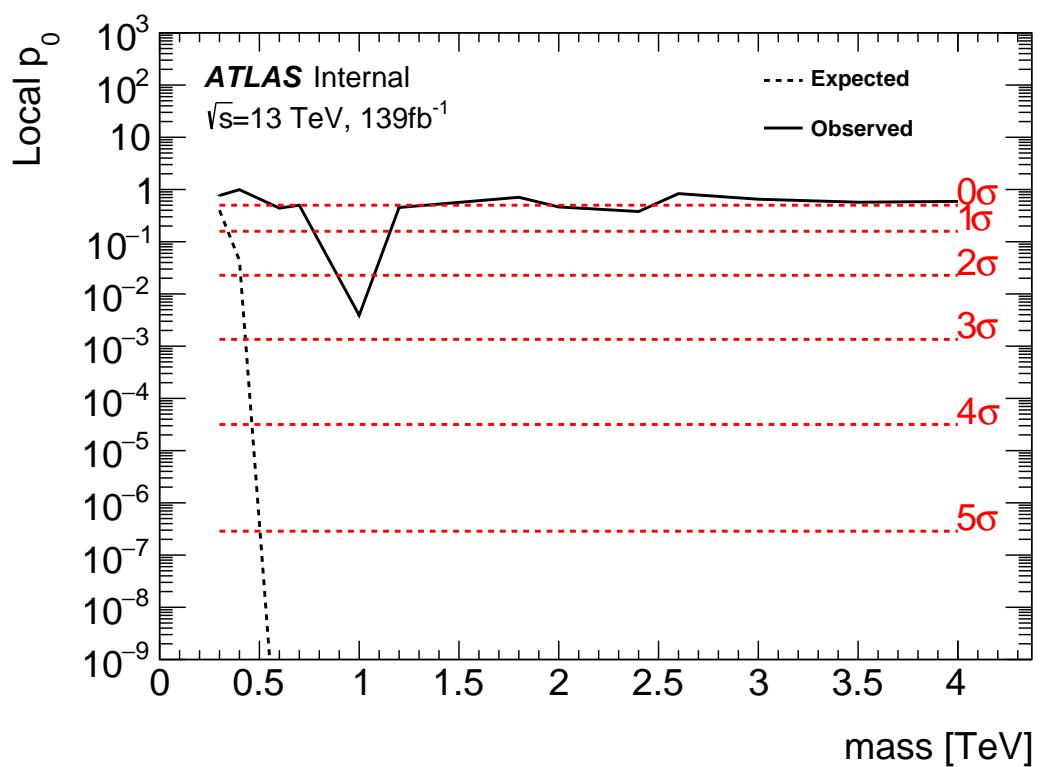

1163 **Statistical Interpretation**

1164 **10.1 Discovery Tests**

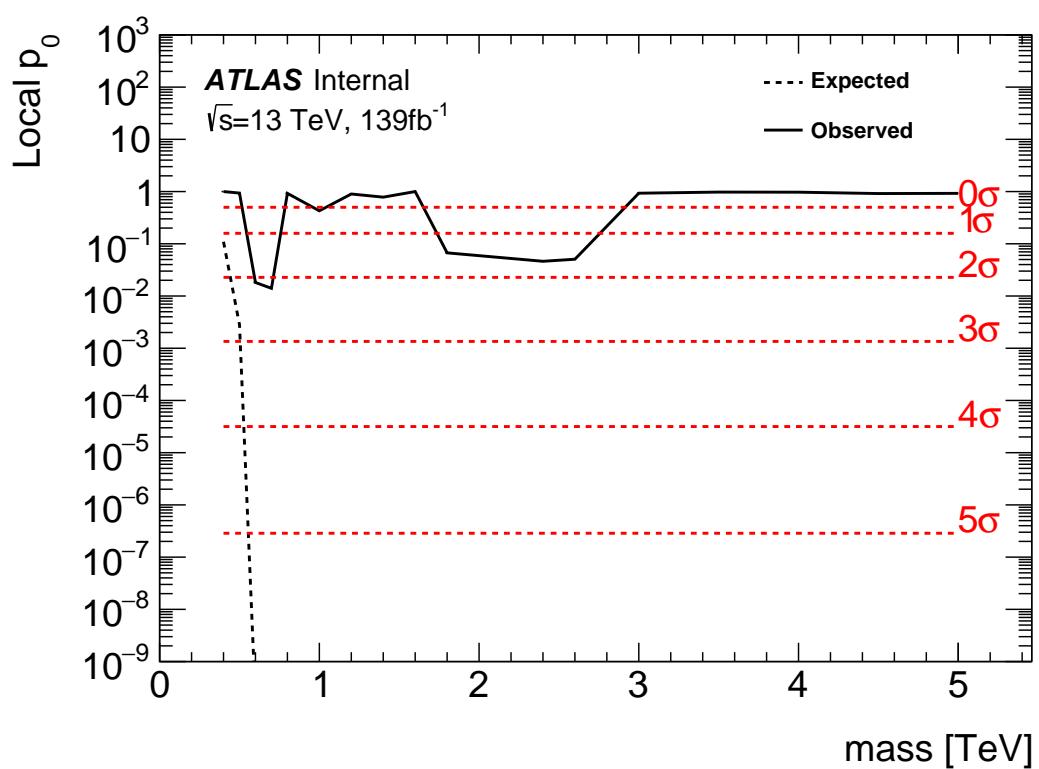

1165 To test for the existence of signal in the observed dataset, the discovery tests  
1166 discussed earlier are used to calculate p-values as a function of resonance mass.  
1167 The results of these tests are shown in Figures 10.1 - 10.5. Across the different  
1168 DY signals the largest excesses are  $\sim 2.2\sigma$  at 600 GeV and  $1.8\sigma$  at 2 TeV. The  
1169 largest excesses for VBF signals are  $< 2.5\sigma$  at for 1 TeV resonances. As these  
1170 deviations do not constitute discoveries, upper limits on  $\mu$  are calculated.

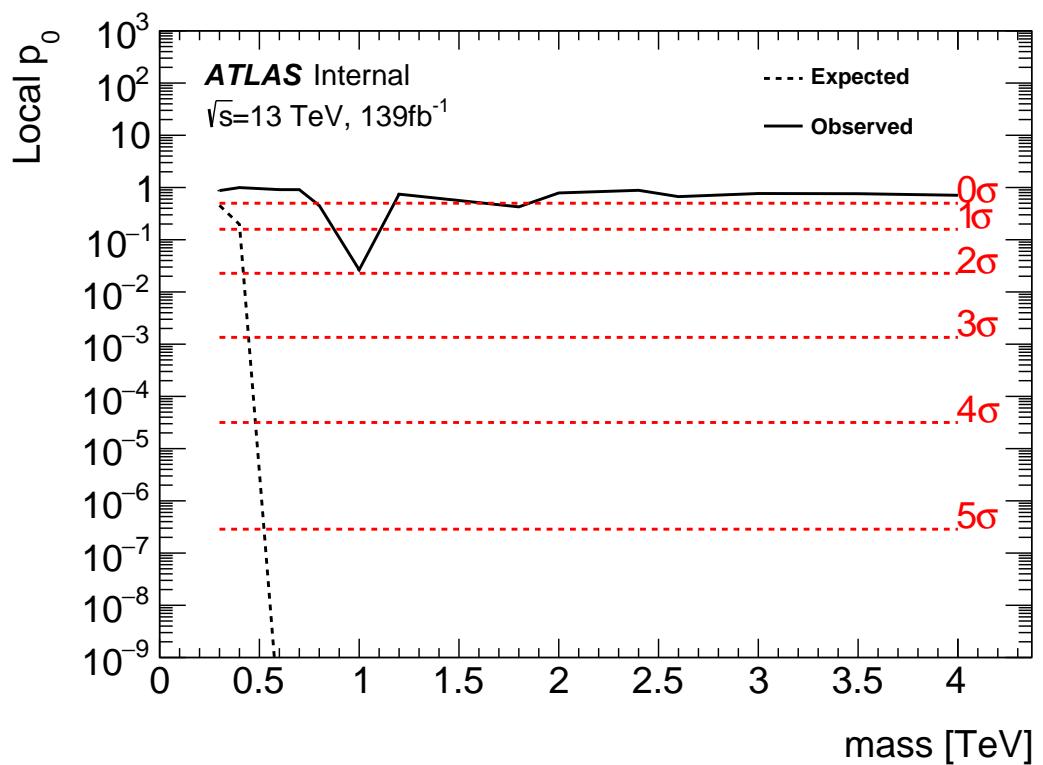

**Figure 10.1:** These plots show the measured  $p_0$  value as a function of resonance mass for HVT Z' DY production.

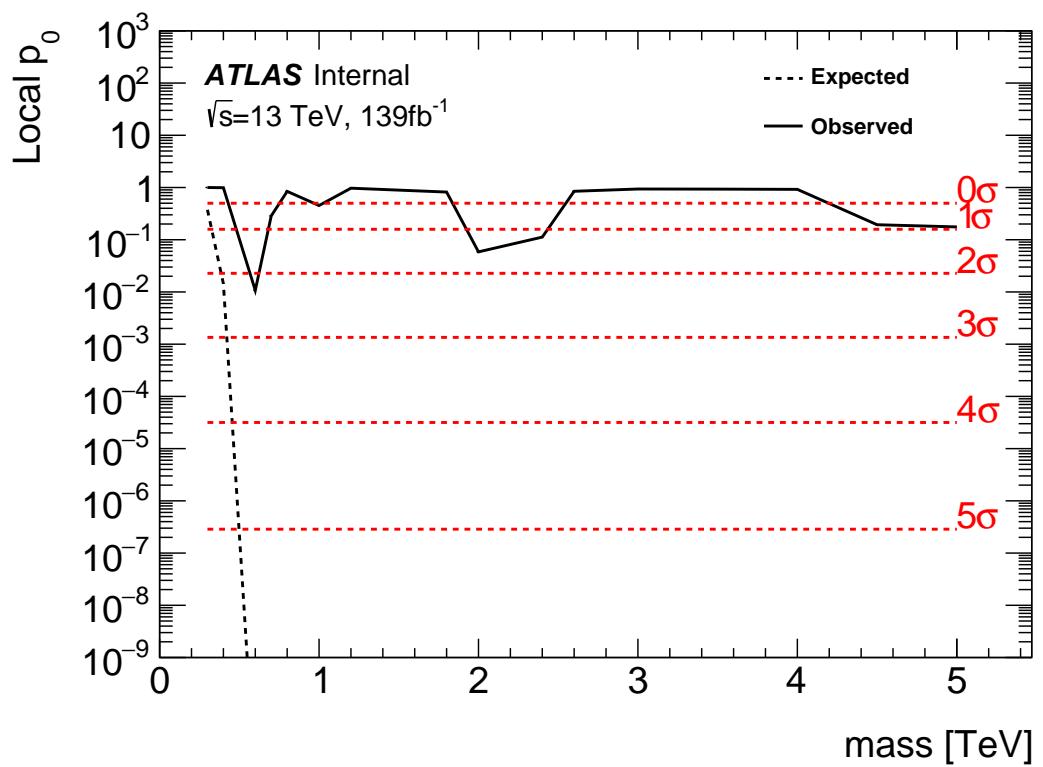

**Figure 10.2:** These plots show the measured  $p_0$  value as a function of resonance mass for HVT Z' VBF production.

**Figure 10.3:** These plots show the measured  $p_0$  value as a function of resonance mass for HVT W' DY production.

**Figure 10.4:** These plots show the measured  $p_0$  value as a function of resonance mass for HVT  $W'$  VBF production.

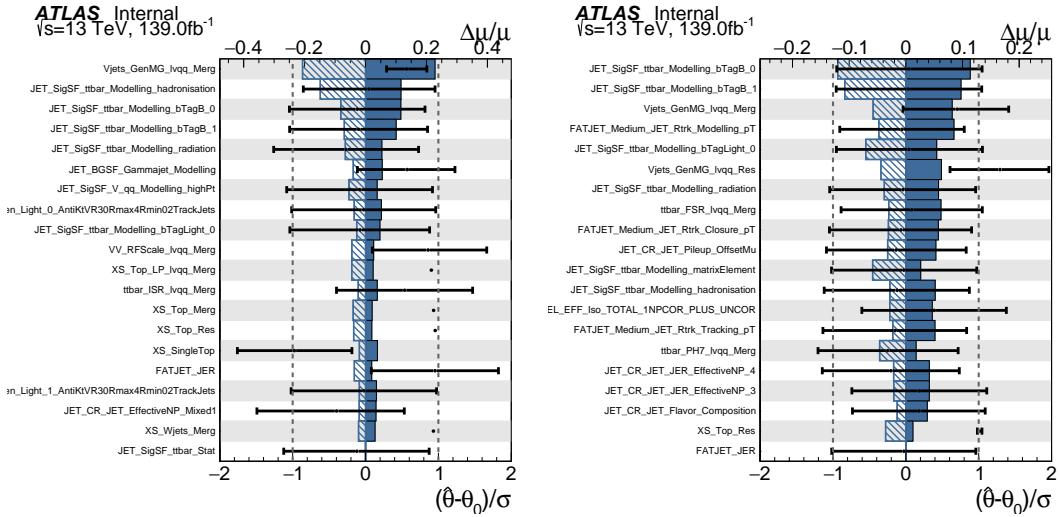

**Figure 10.5:** These plots show the measured  $p_0$  value as a function of resonance mass for the RS Graviton DY production.

## 1171 10.2 Systematic Profiling and Correlations

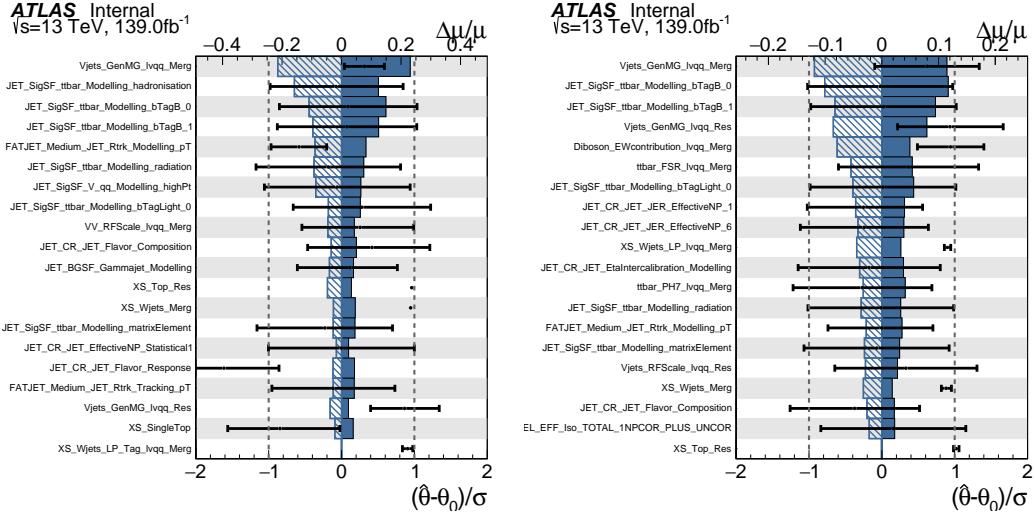

1172 The ranked systematics and their fitted values are shown for the different anal-  
 1173 ysis regions in Figure 10.6 - 10.8. Note that background normalizations for  $W+jets$   
 1174 and  $t\bar{t}$  are left free to float in the fit. This means the nominal normalization val-  
 1175 ues are at one and the uncertainties are not plotted in the ranked plots. Overall,  
 1176 systematics are not pulled outside their uncertainties, especially for highly ranked  
 1177 nuisance parameters.

1178 The correlation between systematics are shown in Figures ???. Correlations  
 1179 between background normalization are expected. The remaining systematic cor-  
 relations are not very strong or unexpected.

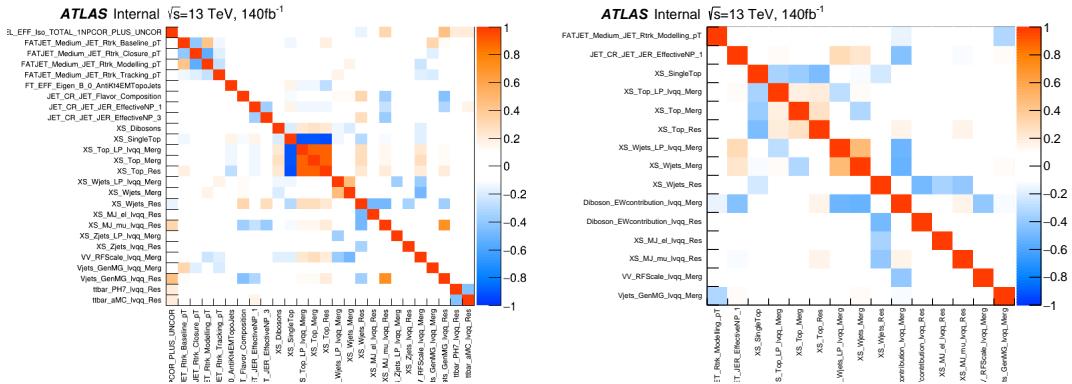

**Figure 10.6:** Ranked systematics and their fitted values for  $WW$  DY (right) and VBF (left) selections.

1180

**Figure 10.7:** Ranked systematics and their fitted values for  $WZ$  DY (right) and VBF (left) selections.

**Figure 10.8:** Correlations between systematics for  $WW$  DY (right) and VBF (left) selections.

### 1181 10.3 Expected and Measured Yields

1182 The yield tables for the four analysis regions are shown in Tables ?? - ?? . The  
 1183 fitted background normalizations are shown in Tables ??-?? . The control region  
 1184  $m_{\ell\nu qq}$  distributions are shown in Figures 10.9 - 10.12. The signal region  $m_{\ell\nu qq}$   
 1185 distributions are shown in Figures 10.13 - ?? .

## 1186 10.4 Limits

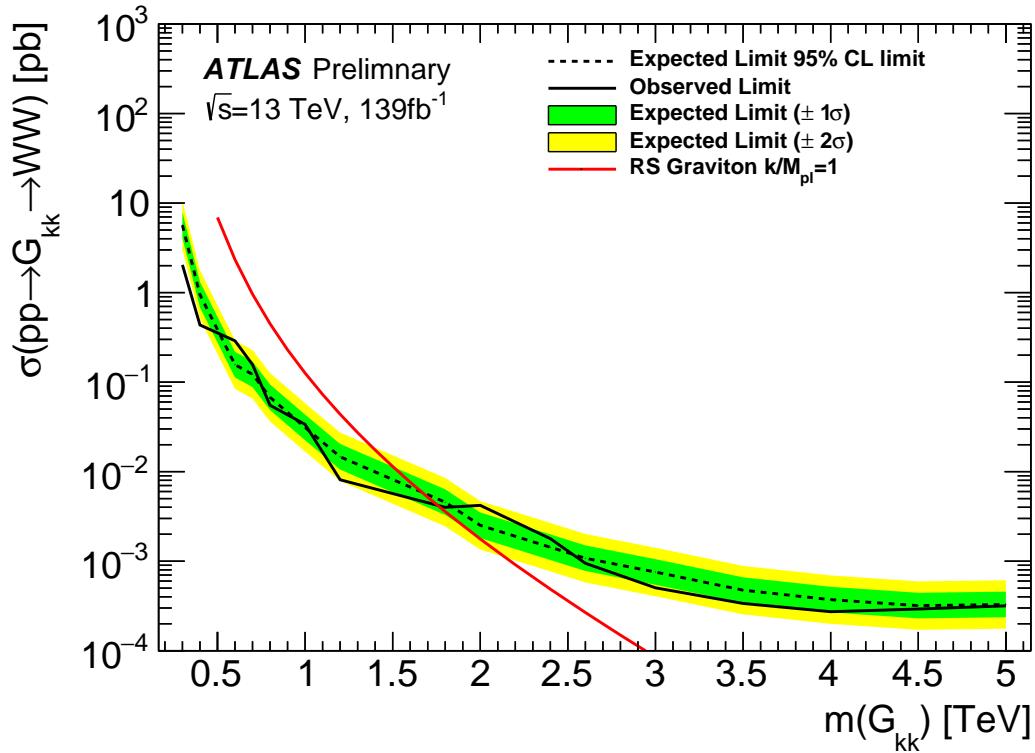

1187 Using the exclusion limits tests discussed previously, exclusion limits are set  
 1188 on  $\mu$  and consequently cross-sections for different signal models. Exclusion limits  
 1189 for the models considered are shown in Figure 10.18 - 10.20. These limits exclude  
 1190 HVT Model A  $W' < \text{blah}$  and  $Z' < \text{blah}$  and Model B  $W' < \text{blah}$  and  $Z' < \text{blah}$ .  
 1191 Randall Sundrum Gravitons are excluded for masses below blah.

**Figure 10.18:** This figure shows theory, expected and observed limits for HVT  $W'$  DY (left) and VBF (right) production.

**Figure 10.19:** This figure shows theory, expected and observed limits for HVT  $Z'$  DY (left) and VBF (right) production.

**Figure 10.20:** This figure shows theory, expected and observed limits for RS Gravitons via DY production.

<sub>1194</sub> **Chapter 11**

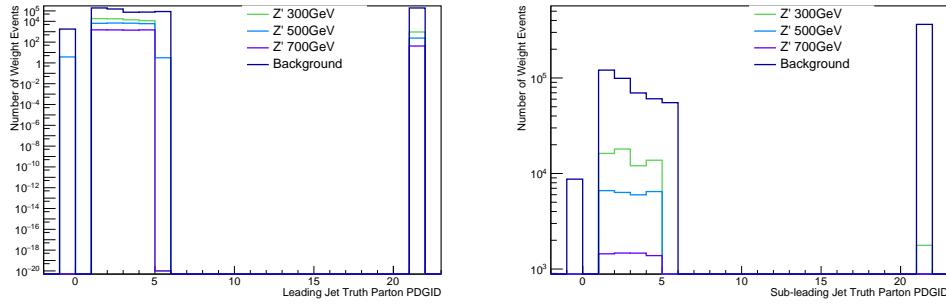

<sub>1195</sub> **Prospects**

<sub>1196</sub> For the resolved analysis, signal jets are quark enriched and background jets are  
<sub>1197</sub> gluon dominated. By classifying jets in the event as quark or gluon initiated, less  
<sub>1198</sub> background would contaminate the signal region. Figure 11.1 shows the PDGID  
<sub>1199</sub> for the truth parton matched to the jet (meaning the highest energy parton in  
<sub>1200</sub> the jet catchment area) in events passing the resolved signal region selections.  
<sub>1201</sub> PDGID = -1 corresponds to pileup jets,  $0 < \text{PDGID} < 6$  correspond to quarks  
<sub>1202</sub> and  $\text{PDGID} = 21$  corresponds to gluons. From this Figure, it is evident that a  
<sub>1203</sub> notable fraction of the background that contaminates the signal region contains  
<sub>1204</sub> gluon jets, especially for the sub-leading jet.

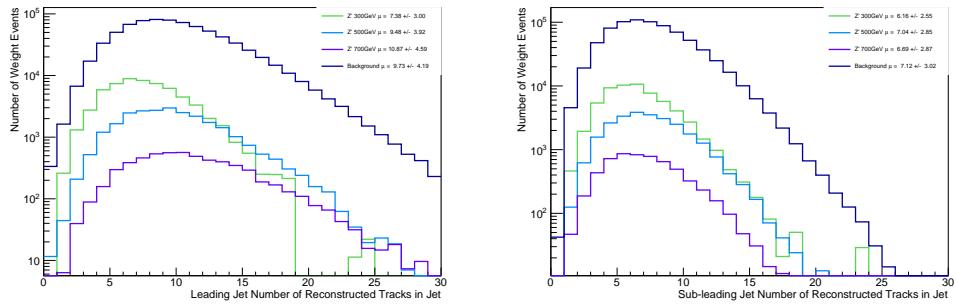

<sub>1205</sub> As gluons jets have more constituents and therefore more tracks ( $n_{trk}$ ), the  
<sub>1206</sub> background jets have more tracks than the signal jets. This is shown in Fig-  
<sub>1207</sub> ure 11.2. Therefore, by cutting on the number of tracks in a jet, quark and gluon  
<sub>1208</sub> jets may be distinguished (i.e. jets with less than a given number of tracks are  
<sub>1209</sub> classified as a quark, otherwise the jet is classified as a gluon.) Moreover, as the  
<sub>1210</sub> momentum of the jet increases the number of tracks also increases logarithmically.  
<sub>1211</sub> Therefore by applying a cut on the number of tracks that scales with the  $\ln(p_T)$   
<sub>1212</sub> is more powerful than a threshold cut on the number of tracks. Figure 11.3-

1213   Figure 11.6 show normalized heat maps of  $\ln(p_T)$  vs the number of reconstructed  
1214   tracks for the background and a 300 GeV Z' signal. In these plots it is evident  
1215   that the number of tracks in the background jets grows more quickly with  $\ln(p_T)$   
1216   than for the signal jets. This is expected given that the signal is quark dominated  
1217   and the background is gluon dominated.

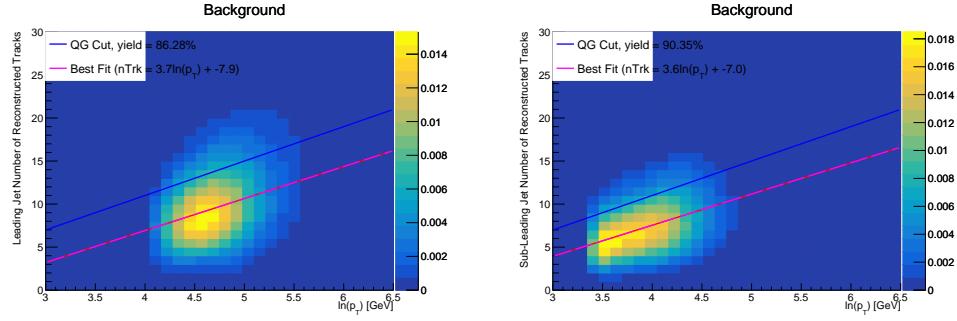

1218   In Figure 11.8 is the ROC Curve for quark gluon tagging with cut on the  
1219   number of tracks in a jet that depends on  $\ln(p_T)$ . The sum of the backgrounds in  
1220   the signal region were used for this curve. Here the quark tagging efficiency is the  
1221   ratio of quarks tagged as quarks to the total number of quarks in the signal region.  
1222   The gluon rejection is calculated as the reciprocal of the gluon tagging efficiency.  
1223   Choosing a 90 efficient working point with a rejection of 1.4 corresponds to a slope  
1224   of 4 and intercept of -5. Focusing on the background in Figure 11.9, this cut helps  
1225   minimize gluon contamination in the signal region. Also, from these heat maps it  
1226   is obvious that the number of tracks in gluon jets grows more quickly than those  
1227   in quark jets.

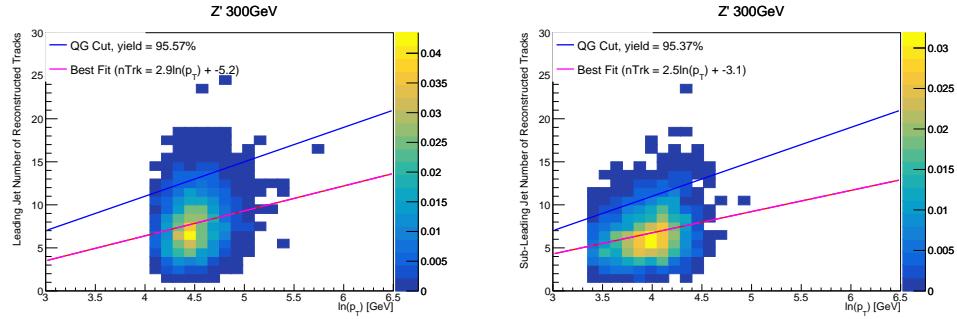

**Figure 11.1:** PDGID of the truth-level parton matched to the small-R jets passing the Resolved GGF WW Signal Region selections for the (a) Leading (b) Sub-Leading jets . These distributions are shown for 300, 500, and 700GeV Z' signals and the background.

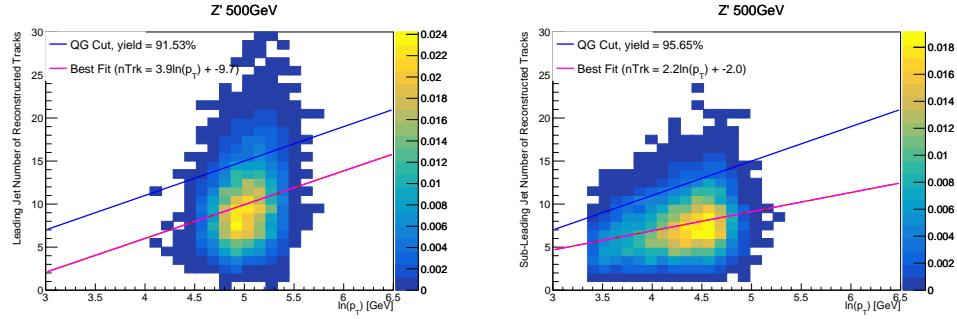

**Figure 11.2:** The number of tracks in small-R jets in events passing the Resolved GGF WW Signal Region selections for the (a) Leading (b) Sub-Leading jets. These distributions are shown for 300, 500, and 700GeV Z' signals and the background.

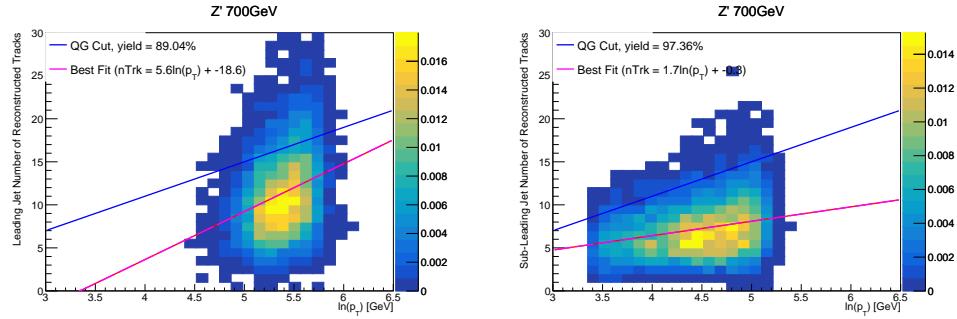

**Figure 11.3:** The number of tracks in background small-R jets in events passing the Resolved GGF WW Signal region selection vs.  $\ln(p_T)$  for (a)Leading (b) Sub-Leading jets. The best fit line for the distribution is also shown, as well as the percentage of jets that pass a cut of number of tracks  $< 4 \times \ln(p_T) - 5$ . Note the number of total entries in these plots has been normalized to one.

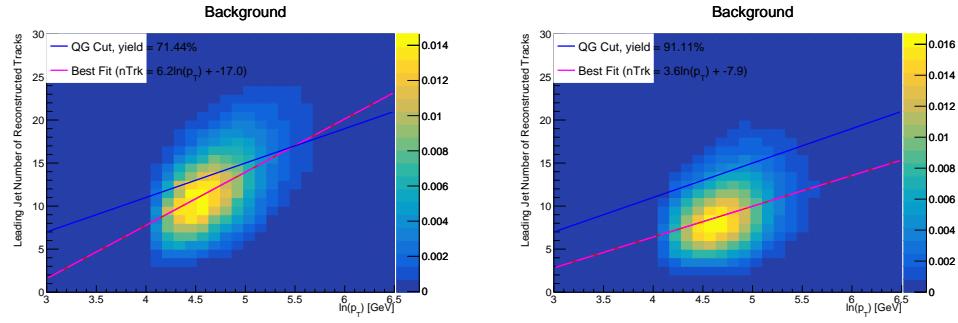

**Figure 11.4:** The number of tracks in small-R jets in 300GeV  $Z'$  events passing the Resolved GGF WW Signal region selection vs.  $\ln(p_T)$  for (a)Leading (b) Sub-Leading jets. The best fit line for the distribution is also shown, as well as the percentage of jets that pass a cut of number of tracks  $< 4 \times \ln(p_T) - 5$ . Note the number of total entries in these plots has been normalized to one.

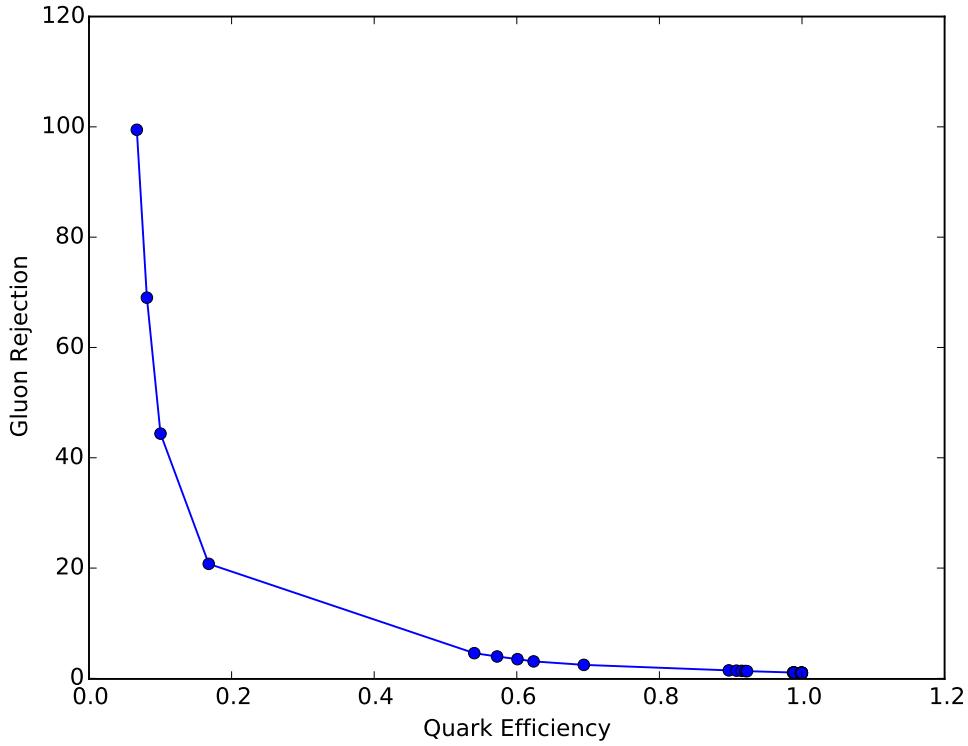

**Figure 11.5:** The number of tracks in small-R jets in 500GeV  $Z'$  events passing the Resolved GGF WW Signal region selection vs.  $\ln(p_T)$  for (a)Leading (b) Sub-Leading jets. The best fit line for the distribution is also shown, as well as the percentage of jets that pass a cut of number of tracks  $< 4 \times \ln(p_T) - 5$ . Note the number of total entries in these plots has been normalized to one.

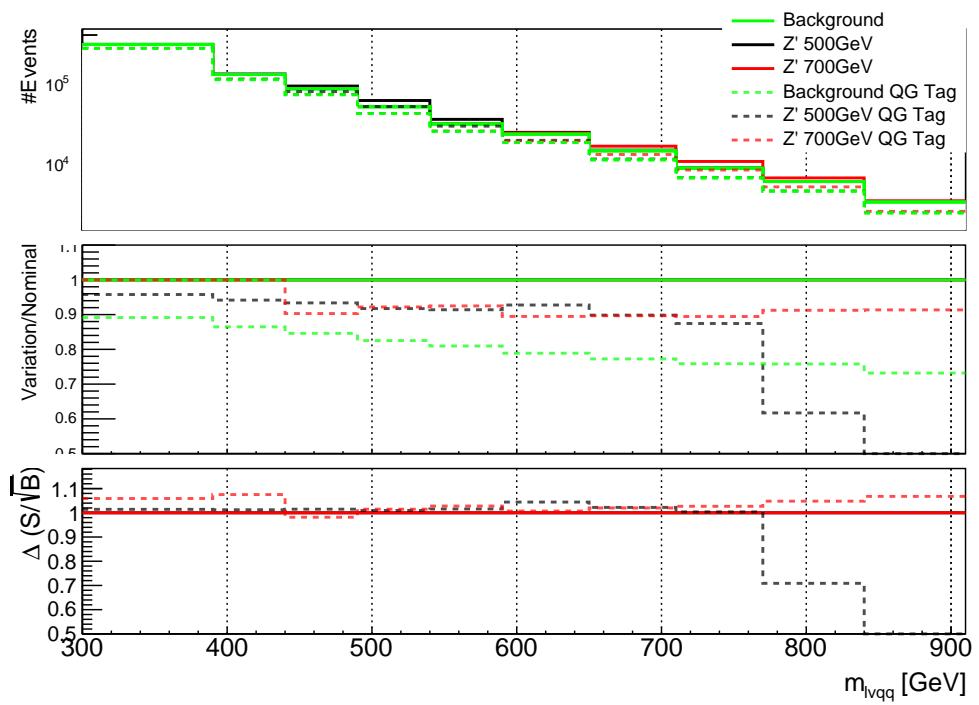

**Figure 11.6:** The number of tracks in small-R jets in 700GeV  $Z'$  events passing the Resolved GGF WW Signal region selection vs.  $\ln(p_T)$  for (a)Leading (b) Sub-Leading jets. The best fit line for the distribution is also shown, as well as the percentage of jets that pass a cut of number of tracks  $< 4 \times \ln(p_T) - 5$ . Note the number of total entries in these plots has been normalized to one.

**Figure 11.7:** The number of tracks in leading small-R jets in background events passing the Resolved GGF WW Signal region selection vs.  $\ln(p_T)$  for (a)Gluons (b) Quarks jets. The best fit line for the distribution is also shown, as well as the percentage of jets that pass a cut of number of tracks  $< 4 \times \ln(p_T) - 5$ .Note the number of total entries in these plots has been normalized to one.

**Figure 11.8:** ROC Curve for Quark and Gluon Tagging with a cut on the number of tracks that depends on the  $\ln(p_T)$ .

**Figure 11.9:** The top panel shows the distribution of  $m_{lvqq}$  with and without quark gluon tagging. The middle panel shows the ratio of the signals and backgrounds with and without quark gluon tagging. The bottom panel shows the change in  $S/\sqrt{B}$  with quark gluon tagging.

<sub>1228</sub> **Chapter 12**

<sub>1229</sub>  **$n_{trk}$  Calibration**

<sub>1230</sub> As tagger based on nTrk cuts on the number of tracks in jets, a quantity that  
<sub>1231</sub> is not known with infinite precision, relevant systematic uncertainties must be  
<sub>1232</sub> evaluated. The sources of uncertainty in  $n_{trk}$  may be split into modeling and  
<sub>1233</sub> experimental uncertainties.

<sub>1234</sub> Modeling uncertainties are obtained by assessing PDF and ME uncertainties  
<sub>1235</sub> on the number of charged particles in particle-level jets in dijet events. The  
<sub>1236</sub> number of charged particles as a function of jet  $p_T$  is calculated using an Iterative  
<sub>1237</sub> Bayesian (IB) technique [cite paper].

<sub>1238</sub> This measurement ([7]) uses the ATLAS 2012 pp collision dataset, correspond-  
<sub>1239</sub> ing to  $20.3/\text{fb}$  at center-of-mass energy  $\sqrt{s} = 8\text{TeV}$ . Monte Carlo (MC) samples  
<sub>1240</sub> are used to determine the response matrix. The MC sample is a dijet sample gen-  
<sub>1241</sub> erated with Pythia 8.175 using CT10 PDF and AU2 tune. The anti- $k_T$  algorithm  
<sub>1242</sub> is used to cluster jets with a radius parameter  $R = 0.4$ . Jets are required to have  
<sub>1243</sub>  $|\eta| < 2.1$ . Tracks in jets are required to have  $p_T > 500\text{MeV}$ ,  $|\eta| < 2.5$ , track-fit  
<sub>1244</sub>  $\chi^2 < 3.0$  and originate from the primary vertex. Matching tracks to jets is accom-  
<sub>1245</sub> plished using ghost-association [cite]. In this technique, jets are re-clustered with  
<sub>1246</sub> the track collection augmented with "ghost" versions of tracks. These "ghosts"

1247 tracks have the same direction as their parent track, but infinitesimal track  $p_T$ .  
1248 This insures meta-jet properties (e.g.  $\eta$ ,  $p_T$ , etc) are unchanged. A track is  
1249 matched to a jet if it's ghost version remains in the jet after re-clustering. Further  
1250 details of the data, object, and event selection may be found in [cite 35].

1251 To select dijet topologies events are required to have at least two jets with  
1252  $p_T > 50\text{GeV}$  that are relatively well-balanced ( $p_T^{\text{lead}}/p_T^{\text{sub-leading}} < 1.5$ ).

1253 In the IB technique, the prior distribution and number of iterations are the  
1254 inputs [cite Bayesian paper]. The IB response matrix connects number of charged  
1255 particles to the number of tracks in jets determined using the simulated samples.  
1256 This response matrix is used to unfold data to extract the  $n_c$ . Before applying  
1257 the response matrix a fake factor is applied. This accounts for jets that pass  
1258 detector level selections, but not particle level selections. Following this, the IB  
1259 method iteratively applies the response matrix using the nominal Pythia 8.175  
1260 sample as a prior. The number of IB iterations is chosen to minimize unfolding  
1261 bias and statistical fluctuations. For this measurement four iterations was found  
1262 to be optimal by minimizing the unfolding bias from pseudodata simulated with  
1263 Herwig++ with a prior from Pythia 8 AU2. Finally, the inefficiency factor is  
1264 applied to account for events passing particle level selection but not detector  
1265 level, yielding the unfolded nCharged distribution.

1266 This process is prone to three main sources of bias: response matrix, correction  
1267 factor, and unfolding procedure uncertainties. The response matrix is sensitive to  
1268 experimental uncertainties impacting jet track reconstruction and calorimeter jet  
1269  $p_T$ . Correction factors are also sensitive to experimental uncertainties (e.g. JES)  
1270 as such uncertainties modify detector level acceptance. Sensitivity to particle level  
1271 acceptance is calculated by comparing Pythia and Herwig. Finally, the bias from  
1272 the IB prior choice is determined by reweighting the particle-level spectrum, so

1273 the simulated detector level spectrum more closely matches the uncorrected data.  
 1274 Unfolding this modified detector-level simulation and comparing it re-weighted  
 1275 particle-level spectrum indicates bias from the prior distribution choice.

1276 A summary of all the systematic uncertainties associated with this unfolding  
 1277 may be found in [ref paper]. Total uncertainties are < 7% for the number of  
 1278 charged particles in jets. The unfolded distribution of the nCharged in jets from  
 1279 data are further analyzed to extract the quark and gluon nCharged distributions.  
 1280 In dijet events, the jet with a larger  $\eta$  is more energetic and therefore more likely  
 1281 to be a quark. This is due to the quarks in protons generally having a larger  
 1282 fraction of the total momentum of the proton constituents. The more central jet  
 1283 is more likely to be a gluon-initiated jet. This correlation between jet  $\eta$  and flavor  
 1284 may then be used to extract nCharged in  $p_T$  bins using:

$$\langle n_c^f \rangle = f_q^f \langle n_c^q \rangle + f_g^f \langle n_c^g \rangle \quad (12.1)$$

1285

$$\langle n_c^c \rangle = f_q^c \langle n_c^q \rangle + f_g^c \langle n_c^g \rangle \quad (12.2)$$

1286 In this equation the f and c subscripts denote the more forward and central  
 1287 jets, respectively. The q and g subscripts denote quark and gluon. The fraction  
 1288 of more forward jets that are say gluons is denoted by  $f_g^f$ . The other relevant jet  
 1289 fractions are denoted with the same naming scheme. Finally,  $\langle n_c \rangle$  is the average  
 1290 number of charged particles in a jet in a given  $p_T$  bin. To show that Eq. (??) may  
 1291 be used to extract quark and gluon  $n_c$  distributions the extracted distributions  
 1292 are compared to  $n_c$  distributions determined using the jet flavor in simulation.  
 1293 Figure [add figure natasha] shows that the extracted and true distributions differ  
 1294 by < 1% over the  $p_T$  ranged probed for this study. Moreover, this implies that  $n_c$   
 1295 depends only on the flavor of the initiating parton and jet  $p_T$ .

1296 These extracted distributions are prone to PDF and ME biases. The bias from

1297 the choice of the CT10 PDF for the Pythia sample is accounted for by comparing  
1298 quark/gluon fractions for the nominal CT10 sample with its eigenvector variations.  
1299 Comparing the quark/gluon fractions from Pythia 8 and Herwig++ quantify the  
1300 uncertainty from the ME calculation. These uncertainties are added in quadra-  
1301 ture with the unfolding uncertainty to give the total modelling uncertainty on  
1302 the extracted  $n_c$  distribution. This is shown in Figure 13.2.

1303 To apply these uncertainties in  $n_c$  distributions in data, per-jet event weights  
1304 are associated with each uncertainty according to:

$$w_i(n_c) = \frac{P(n_c | < n_c > \pm \sigma_{n_c}^i)}{P(n_c | < n_c >)} \quad (12.3)$$

1305 In Eq. (??), i denotes the uncertainty considered, P is the Poisson probability,  
1306 and  $\sigma_{n_c}^i$  represents the average impact of the uncertainty on  $n_c$ .

1307 The previous uncertainties described accounted for modeling uncertainty as-  
1308 sociated with the number of charged particles in a jet. However,  $n_c$  is not a  
1309 measurable quantity. Instead the number of tracks in a jet is measured, which is  
1310 a proxy for  $n_c$ . Therefore the uncertainties associated with the measurement of  
1311 nTracks must also be considered ([9]). These uncertainties were calculated using  
1312 a Pythia 8 dijet sample with NNPDF 23. Track reconstruction efficiency and fake  
1313 rates are the dominant sources of nTrack uncertainties.

1314 The track reconstruction efficiency is effected by the uncertainty of the de-  
1315 scription of the ID material in simulation and the modeling of charged-particle  
1316 interactions with this material. These uncertainties are accounted for by varying  
1317 the ID material by 5-25% (dependent on the region of the detector considered).  
1318 The difference in the tracking efficiency between the nominal and varied simula-  
1319 tion give the uncertainty on the track reconstruction efficiency. Another important  
1320 source of track reconstruction efficiency arises in the core of jets. The high density

1321 of tracks in the jet cores can cause ID clusters to merge. The fraction of lost tracks  
 1322 due to merging is given by the fraction of tracks that have a charge of two mini-  
 1323 mum ionizing particles. This quantity is compared between data and simulation  
 1324 resulting in an uncertainty of 0.4% on tracks with  $\Delta R < 0.1$ . Combining these  
 1325 effects gives a total uncertainty as a function of  $p_T$  and  $\eta$  that is generally  $< 2\%$   
 1326 [references figure 44 from [9]).]

1327       Fake tracks are the other dominant source of nTrk uncertainty. Fake tracks  
 1328 are tracks that cannot be associated to a single particle. Often these tracks are a  
 1329 result of random combinations of hits from charged particles that overlap in space.  
 1330 In dense environments, such as the core of jets or high-pileup environments, fake  
 1331 tracks are more likely. Fake tracks are estimated with a 'control region method'  
 1332 which is briefly summarized here [[8]]. By applying a series of track selections  
 1333 to enrich the fraction of fake tracks (e.g.  $|d_0| > 0.1$ , track  $\chi^2 > 1.4$ , etc) in  
 1334 simulation, templates for fake track parameters are calculated. These templates  
 1335 are then fit to data to determine the fraction of fake tracks. On average the fake  
 1336 rate is found to be 30% (independent of  $p_T$  and  $\eta$ ).

1337       To assess the impact of these two detector level uncertainties, tracks are ran-  
 1338 domly dropped according to the rates described above. Reconstruction and fake  
 1339 uncertainties both lower the number of tracks, hence these uncertainties are one-  
 1340 sided. By dropping tracks in this way a varied nTrk distribution is calculated for  
 1341 both uncertainties. The associated per-jet event weights are then calculated in  
 1342 the same way as the modeling weights as:

$$w_i(n_c) = \frac{P(n_{trk} | < n_{trk} > \pm \sigma_{n_{trk}}^i)}{P(n_{trk} | < n_{trk} >)} \quad (12.4)$$

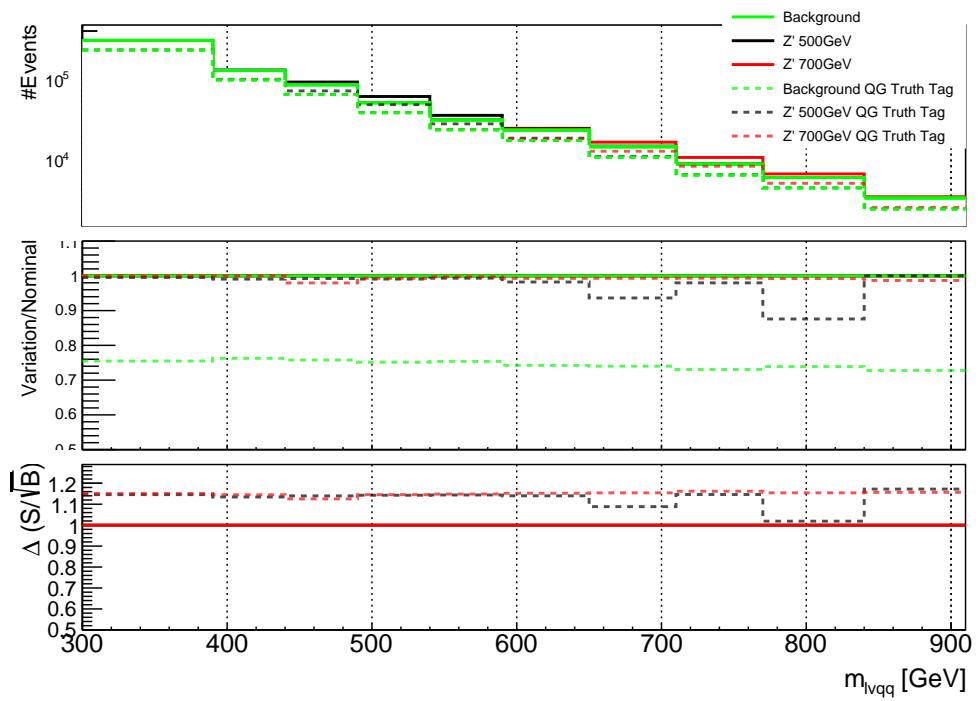

1343       Adding the modeling and detector level uncertainties in quadrature gives the  
 1344 overall nTrack uncertainty. The effects of the individual uncertainties on the nTrk

1345 distributions can be seen in Fig 13.4. Fig 13.3 shows the  $m_{lvqq}$  and nTrk distri-  
1346 butions for the W and Top control regions before likelihood fitting. In these plots  
1347 the nTrk uncertainties improve agreement between data and MC. The remaining  
1348 differences are likely covered by likelihood fitting and improving the analysis itself.

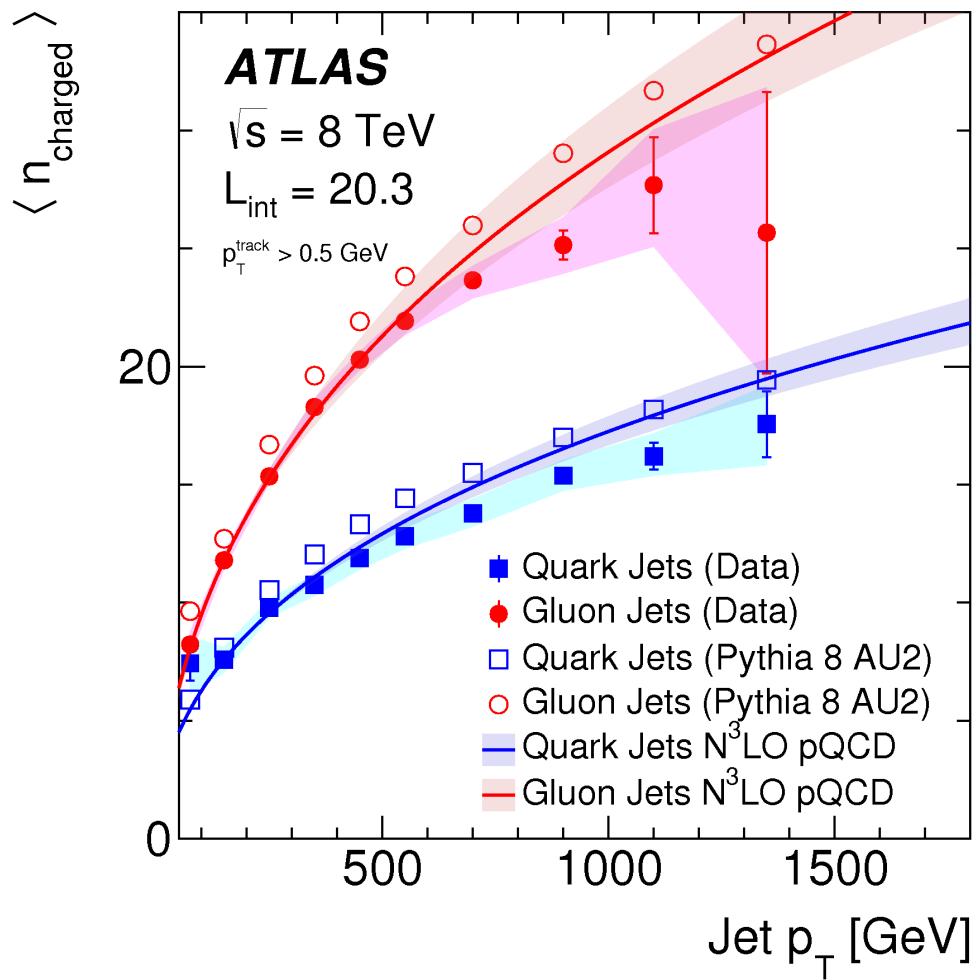

<sub>1349</sub> **Chapter 13**

<sub>1350</sub> **Application**

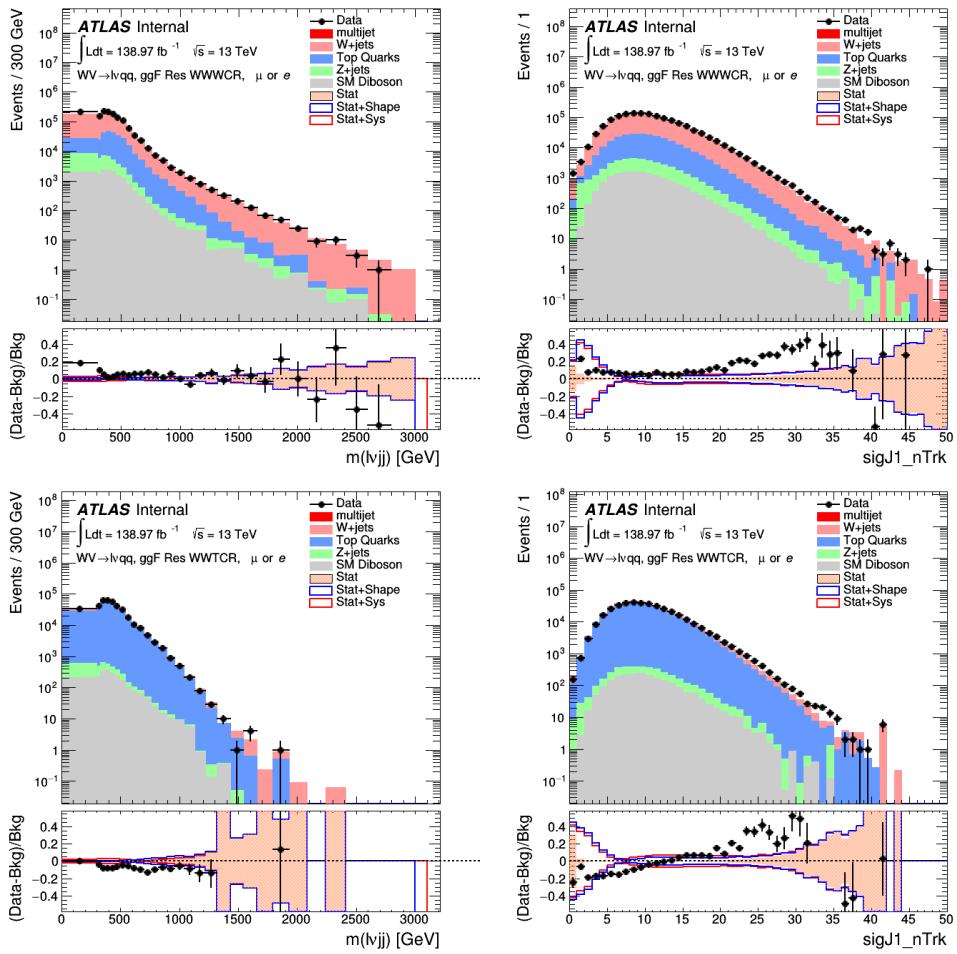

<sub>1351</sub> Using the 90% WP of the  $n_{trk}$  tagger improves  $S/\sqrt{B}$  is  $< 3\%$  as shown in  
<sub>1352</sub> Figure 11.9. Although,  $n_{trk}$  is the single most powerful discriminating variable  
<sub>1353</sub> for quark and gluon jets, the addition of other jet variables would improve the  
<sub>1354</sub> classification efficiency. Figure 13.1 shows the possible improvement of 10%  
<sub>1355</sub> in jet classification using the truth label of the jets to classify jets. This type of  
<sub>1356</sub> improvement is possible by using variables such as jet width, and energy correlata-  
<sub>1357</sub> tors. Figure [add BDT figure/use 1612.01551.pdf] shows for a 90% quark tagging  
<sub>1358</sub> efficiency for a 100 GeV jet, a BDT improve the gluon rejection by 0.4. Once this  
<sub>1359</sub> tagger is calibrated it would improve the analysis sensitivity of this channel.

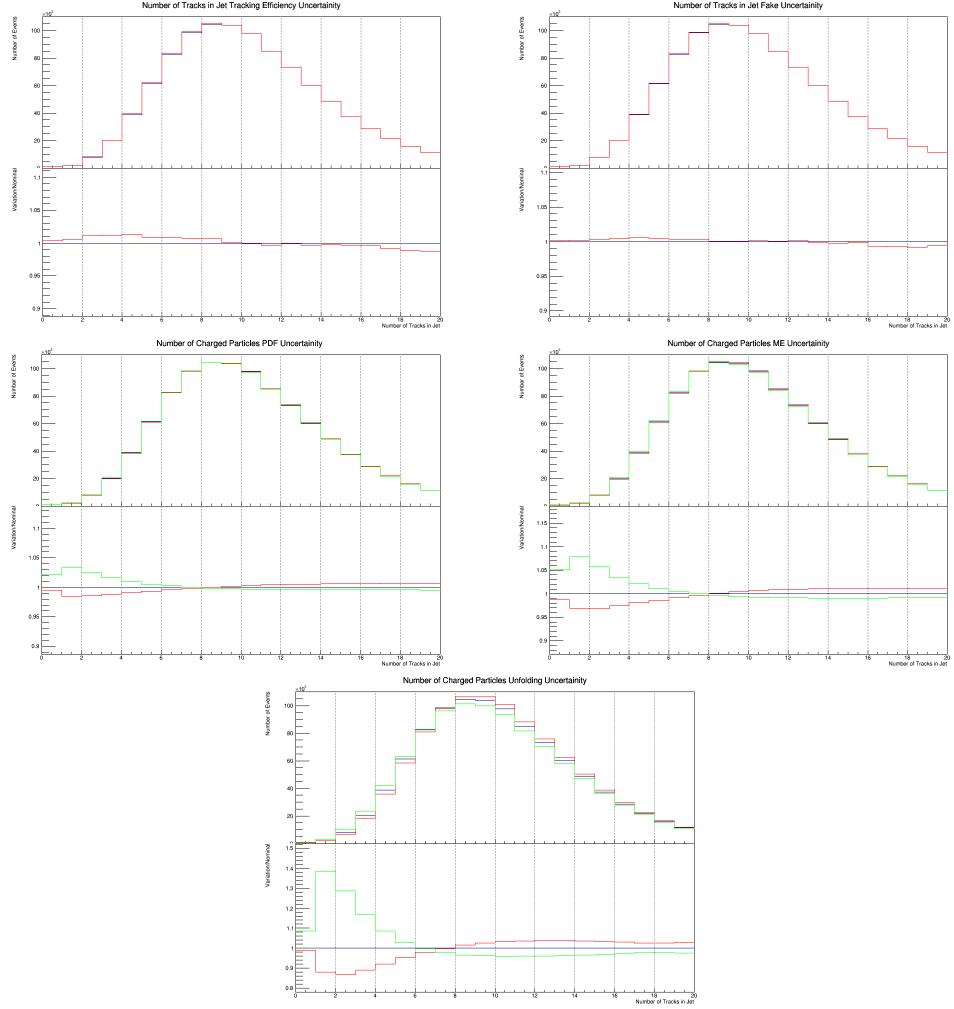

**Figure 13.1:** The top panel shows the distribution of  $m_{lvqq}$  with and without requiring jets to be true quarks. The middle panel shows the ratio of the signals and backgrounds with and without requiring jets to be true quarks. The bottom panel shows the change in  $S/\sqrt{B}$  when requiring jets to be true quarks..
