| 6.8 | Schematic of HCAL. | 51 |
| 6.9 | Schematic of Muon Spectrometer [cite G35] | 54 |
| 6.10 | Schematic of MDT chamber. [cite G35] | 55 |
| 6.11 | Schematic of RPC chamber, which is used for triggering in the central region of the detector [cite G35]. | 55 |
| 6.12 | Schematic of TGC chamber, which is used for triggering in the muon end-cap region. [cite G35] | 56 |
| 6.13 | Layout of ATLAS magnet systems. | 57 |
| 7.1 | Integrated luminosity for data collected from ATLAS from 2011 - 2018 | 61 |
| 7.2 | Mean number of interactions per crossing for data collected from ATLAS from 2011 - 2018 | 62 |
| 8.1 | This figure shows the breakdown of the muon reconstruction efficiency scale factor measured in $Z \rightarrow \mu\mu$ as a function of p_T [5]. | 66 |
| 8.2 | [8] This diagram shows the calibration stages for EM jets. | 68 |
| 8.3 | The upper cut on D_2 (a) and jet mass window cut i.e. the upper and lower boundary of the mass (b) of the W -tagger as a function of jet p_T . Corresponding values for Z -tagger are shown in (c) and (d). The optimal cut values for maximum significance are shown as solid markers and the fitted function as solid lines. Working points from $VV \rightarrow JJ$ [ATLAS-HDBS-2018-31-002] is also shown as dashed lines as a reference. Natasha reword? | 71 |
| 8.4 | Natasha write caption | 72 |
| 9.1 | RNN architecture. Natasha add caption | 82 |

| | | |
|------|---|----|
| 9.2 | This figure shows the embedded logic in LSTM cells. This image was taken from [23], where a more in depth discussion about LSTMs may be found. | 83 |
| 9.3 | RNN Score distribution for ggF and VBF signals and backgrounds. | 84 |
| 9.4 | ROC curve using k-fold validation for RNN. | 85 |
| 9.5 | Comparison of GGF Z' limits for different RNN score selections. The bottom panel shows the ratio of the upper limits set for different RNN cuts to the cut-based analysis. In this panel smaller numbers, indicate that the expected upper limit is smaller than the cut-based analysis, which is desired. | 86 |
| 9.6 | Event Categorization. Natasha write more. | 89 |
| 9.7 | Selection acceptance times efficiency for the $W' \rightarrow WZ \rightarrow \ell\nu qq$ events from MC simulations as a function of the W' mass for Drell-Yan (left) and VBF production (right), combining the merged HP and LP signal regions of the $WW \rightarrow \ell\nu J$ selection and the resolved regions of the $WW \rightarrow \ell\nu jj$ selection. Note: the VBF selection acceptance for the DY W' is approximately zero in the left plot. | 90 |
| 9.8 | Selection acceptance times efficiency for the $G \rightarrow WW \rightarrow \ell\nu qq$ events from MC simulations as a function of the G mass for (a) Drell-Yan and (b) VBF production, combining the merged HP and LP signal regions of the $WW \rightarrow \ell\nu J$ selection and the resolved regions of the $WW \rightarrow \ell\nu jj$ selection. Note: the VBF selection acceptance for the ggF G'_{KK} is approximately zero in the left plot. | 91 |
| 10.1 | Data MC comparison for the merged WW HP TCR. The bottom panel shows the ratio of the difference between data and simulation to simulation. The red bands include the all systematic and statistical uncertainties on the background. | 94 |

| | |
|--|-----|
| 10.2 Data MC comparison for the merged WW LP TCR. The bottom panel shows the ratio of the difference between data and simulation to simulation. The red bands include the all systematic and statistical uncertainties on the background. | 95 |
| 10.3 Data MC comparison for the merged WZ HP TCR. The bottom panel shows the ratio of the difference between data and simulation to simulation. The red bands include the all systematic and statistical uncertainties on the background. | 96 |
| 10.4 Data MC comparison for the merged WZ LP TCR. The bottom panel shows the ratio of the difference between data and simulation to simulation. The red bands include the all systematic and statistical uncertainties on the background. | 97 |
| 10.5 Data MC comparison for the resolved WW TCR. The bottom panel shows the ratio of the difference between data and simulation to simulation. The red bands include the all systematic and statistical uncertainties on the background. | 98 |
| 10.6 Data MC comparison for the resolved WZ TCR. The bottom panel shows the ratio of the difference between data and simulation to simulation. The red bands include the all systematic and statistical uncertainties on the background. | 99 |
| 10.7 The E_T^{miss} distribution in MJCR for 2017 data in the electron channel(left), muon channel with W-boson pT < 150 GeV (center) and > 150 GeV (right). Multi-jet templates are given by the difference between the data and simulated distributions. | 102 |
| 10.8 Postfit Data/MC comparison of distributions of E_T^{miss} , m_T^W , lepton and neutrino p_T , $m_{\ell\nu jj}$, lepton- ν angular distance in the WW electron channel. The MJ template is obtained from the pre-MJ-fit. | 103 |
| 10.9 Postfit Data/MC comparison of distributions of E_T^{miss} , m_T^W , lepton and neutrino p_T , $m_{\ell\nu jj}$, lepton- ν angular distance in the WW muon channel. The MJ template is obtained from the pre-MJ-fit. | 104 |

| | |
|--|-----|
| 10.10 Postfit Data/MC comparison of distributions of E_T^{miss} , m_T^W , lepton and neutrino p_T , $m_{\ell\nu jj}$, lepton- ν angular distance in the WZ untag electron channel. The MJ template is obtained from the pre-MJ-fit. | 105 |
| 10.11 Postfit Data/MC comparison of distributions of E_T^{miss} , m_T^W , lepton and neutrino p_T , $m_{\ell\nu jj}$, lepton- ν angular distance in the WZ untag muon channel. The MJ template is obtained from the pre-MJ-fit. | 106 |
| 10.12 Postfit Data/MC comparison of distributions of E_T^{miss} , m_T^W , lepton and neutrino p_T , $m_{\ell\nu jj}$, lepton- ν angular distance in the WZ untag electron channel. The MJ template is obtained from the pre-MJ-fit. | 107 |
| 10.13 Postfit Data/MC comparison of distributions of E_T^{miss} , m_T^W , lepton and neutrino p_T , $m_{\ell\nu jj}$, lepton- ν angular distance in the WZ untag muon channel. The MJ template is obtained from the pre-MJ-fit. | 108 |
| 10.14 Postfit Data/MC comparison of distributions of E_T^{miss} , m_T^W , lepton and neutrino p_T , $m_{\ell\nu jj}$, lepton- ν angular distance in the VBF WW electron channel. The MJ template is obtained from the pre-MJ-fit. | 109 |
| 10.15 Postfit Data/MC comparison of distributions of E_T^{miss} , m_T^W , lepton and neutrino p_T , $m_{\ell\nu jj}$, lepton- ν angular distance in the VBF WW muon channel. The MJ template is obtained from the pre-MJ-fit. | 110 |
| 10.16 Postfit Data/MC comparison of distributions of E_T^{miss} , m_T^W , lepton and neutrino p_T , $m_{\ell\nu jj}$, lepton- ν angular distance in the VBF WZ electron channel. The MJ template is obtained from the pre-MJ-fit. | 111 |
| 10.17 Postfit Data/MC comparison of distributions of E_T^{miss} , m_T^W , lepton and neutrino p_T , $m_{\ell\nu jj}$, lepton- ν angular distance in the VBF WZ muon channel. The MJ template is obtained from the pre-MJ-fit. | 112 |
| 11.1 The $W/Z+jet$ systematics for the a) Merged ggF, b) Resolved ggF, c) Merged VBF, and d) Resolved VBF regions. The top subplot shows the nominal and variation distributions/bands, the middle shows the ratio of the two, and the final shows just the shape of the envelope (the final uncertainty). | 118 |

| | |
|---|-----|
| 11.2 The two-point generator comparison between Sherpa and MadGraph for the W/Z+jet samples in the a) Merged ggF, b) Resolved ggF, c) Merged VBF, and d) Resolved VBF regions. The normalization of the Madgraph sample is set to the Sherpa value to consider only shape effects. The bottom inset shows the ratio of the two. | 119 |
| 11.3 Ratio between the variations of generator (red) and hadronization (blue) variations for the Merged regime for $t\bar{t}$ sample. | 120 |
| 11.4 Ratio between the variations of generator (red) and hadronization (blue) variations for the Resolved regime for $t\bar{t}$ sample. | 120 |
| 11.5 Ratio between the variations of ISR up (red) and down (blue) variations for the Merged regime for $t\bar{t}$ sample. | 121 |
| 11.6 Ratio between the variations of ISR up (red) and down (blue) variations for the Resolved regime for $t\bar{t}$ sample. | 122 |
| 11.7 Ratio between the variations of FSR up (red) and down (blue) variations for the Merged regime for $t\bar{t}$ sample. | 123 |
| 11.8 Ratio between the variations of FSR up (red) and down (blue) variations for the Resolved regime for $t\bar{t}$ sample. | 123 |
| 12.1 The HVT signal mass resolution as a function of mass fit with a straight line in the Resolved ggF region (left) and VBF (right) region. | 127 |
| 12.2 The HVT signal mass resolution as a function of mass fit with a straight line in the Merged ggF region (left) and VBF (right) region. | 127 |
| 13.1 This figure shows the distribution of $m_{\ell\nu qq}$ in the DY WW control regions. | 140 |
| 13.2 This figure shows the distribution of $m_{\ell\nu qq}$ in the DY WZ control regions. | 141 |

| 13.5 This figure shows the distribution of $m_{\ell\nu qq}$ in the GGF WW signal regions. | 144 |
| 13.6 This figure shows the distribution of $m_{\ell\nu qq}$ in the GGF WZ Untag signal regions. | 144 |
| 13.7 This figure shows the distribution of $m_{\ell\nu qq}$ in the GGF WZ Tag signal regions. | 145 |
| 13.8 This figure shows the distribution of $m_{\ell\nu qq}$ in the VBF WZ Tag signal regions. | 145 |
| 13.9 This figure shows the distribution of $m_{\ell\nu qq}$ in the VBF WZ Tag signal regions. | 146 |
| 13.10 Ranked systematics and their fitted values for WW DY (right) and VBF (left) selections. | 147 |
| 13.11 Ranked systematics and their fitted values for WZ DY (right) and VBF (left) selections. | 147 |
| 13.12 Correlations between systematics for WW DY (right) and VBF (left) selections. | 148 |
| 13.13 These plots show the measured p_0 value as a function of resonance mass for HVT Z' DY production. | 149 |
| 13.14 These plots show the measured p_0 value as a function of resonance mass for HVT Z' VBF production. | 150 |
| 13.15 These plots show the measured p_0 value as a function of resonance mass for HVT W' DY production. | 151 |
| 13.16 These plots show the measured p_0 value as a function of resonance mass for HVT W' VBF production. | 152 |
| 13.17 These plots show the measured p_0 value as a function of resonance mass for the RS Graviton DY production. | 153 |
| 13.18 This figure shows theory, expected and observed limits for HVT W' DY (left) and VBF (right) production. | 154 |

| | |
|--|-----|
| 13.19 This figure shows theory, expected and observed limits for HVT Z' DY (left) and VBF (right) production. | 155 |
| 13.20 This figure shows theory, expected and observed limits for RS Gravitons via DY production. | 155 |
| 14.1 PDGID of the truth-level parton matched to the small-R jets passing the Resolved GGF WW Signal Region selections for the (a) Leading (b) Sub-Leading jets . These distributions are shown for 300, 500, and 700GeV Z' signals and the background (all simulated backgrounds that pass SR selections). | 159 |
| 14.2 The number of tracks in small-R jets in events passing the Resolved GGF WW Signal Region selections for the (a) Leading (b) Sub-Leading jets. These distributions are shown for 300, 500, and 700GeV Z' signals and the background. | 159 |
| 14.3 The number of tracks in background small-R jets in events passing the Resolved GGF WW Signal region selection vs. $\ln(p_T)$ for (a)Leading (b) Sub-Leading jets. The best fit line for the distribution is also shown, as well as the percentage of jets that pass a cut of number of tracks $< 4 \times \ln(p_T) - 5$. Note the number of total entries in these plots has been normalized to one. | 160 |
| 14.4 The number of tracks in small-R jets in 300GeV Z' events passing the Resolved GGF WW Signal region selection vs. $\ln(p_T)$ for (a)Leading (b) Sub-Leading jets. The best fit line for the distribution is also shown, as well as the percentage of jets that pass a cut of number of tracks $< 4 \times \ln(p_T) - 5$.Note the number of total entries in these plots has been normalized to one. | 160 |

| | |
|---|-----|
| 14.5 The number of tracks in small-R jets in 500GeV Z' events passing the Resolved GGF WW Signal region selection vs. $\ln(p_T)$ for (a)Leading (b) Sub-Leading jets. The best fit line for the distribution is also shown, as well as the percentage of jets that pass a cut of number of tracks $< 4 \times \ln(p_T) - 5$. Note the number of total entries in these plots has been normalized to one. | 161 |
| 14.6 The number of tracks in small-R jets in 700GeV Z' events passing the Resolved GGF WW Signal region selection vs. $\ln(p_T)$ for (a)Leading (b) Sub-Leading jets. The best fit line for the distribution is also shown, as well as the percentage of jets that pass a cut of number of tracks $< 4 \times \ln(p_T) - 5$. Note the number of total entries in these plots has been normalized to one. | 161 |
| 14.7 ROC Curve for Quark and Gluon Tagging with a cut on the number of tracks that depends on the $\ln(p_T)$ | 162 |
| 14.8 The top panel shows the distribution of m_{lvqq} with and without quark gluon tagging. The middle panel shows the ratio of the signals and backgrounds with and without quark gluon tagging. The bottom panel shows the change in S/\sqrt{B} with quark gluon tagging. | 163 |
| 16.1 The top panel shows the distribution of m_{lvqq} with and without requiring jets to be true quarks. The middle panel shows the ratio of the signals and backgrounds with and without requiring jets to be true quarks. The bottom panel shows the change in S/\sqrt{B} when requiring jets to be true quarks. | 171 |
| 16.2 Unfolded and extracted n_C qg dstbs. | 172 |
| 16.3 PDGID of the truth-level parton matched to the small-R jets passing the Resolved GGF WW Signal Region selections for the (a) Leading (b) Sub-Leading jets . These distributions are shown for 300, 500, and 700GeV Z' signals and the background. | 173 |

List of Tables

| | | |
|------|--|-----|
| 2.1 | Representations of the SM fermions under $SU(3)_C \times SU(2)_L \times U(1)_Y$ gauge symmetry group. Rows are correspond to different weak isospin states and columns to different QCD color states. | 13 |
| 9.1 | The list of triggers used in the analysis. | 79 |
| 9.2 | Summary of selection criteria used to define the signal region (SR), W +jets control region (W CR) and $t\bar{t}$ control region ($t\bar{t}$ CR) for merged 1-lepton channel. | 88 |
| 9.3 | The list of selection cuts in the resolved analysis for the WW and WZ signal regions (SR), W +jets control region (WR) and $t\bar{t}$ control region (TR). | 89 |
| 10.1 | Definitions of “inverted” leptons used in multijet control region. For the inverted muon selection, $ptvarcone30$ is given by sum of the p_T of tracks in a cone around the muon candidate divided by the muon p_T . The size of the cone, δR used is $10\text{GeV}/p_T^\mu$ or 0.3, whichever is smaller. So, as the p_T of the muon increases, the cone size used decreases. This is useful as more boosted muons are more likely to be produced in dense environments and using a smaller cone size more accurately determines the quality of the muon. | 101 |

| | |
|--|-----|
| 10.2 Fit validation result in WCRs for 2015+16 data. The fit is done in various WCRs, in order to obtain the corresponding scale factors for MJ templates: ggF resolved WCR for the $WW \rightarrow lvqq$ selection, ggF resolved untagged WCR for the $WZ \rightarrow lvqq$ selection, ggF resolved tagged WCR for the $WZ \rightarrow lvqq$ selection, VBF resolved WCR for the $WW \rightarrow lvqq$ selection, and VBF resolved WCR for the $WZ \rightarrow lvqq$ selection. Post-fit event yields for electroweak processes and MJ contributions are shown. The SF column shows the corresponding normalization scale factors for electroweak processes from the fit. R.U. stands for relative uncertainty. | 113 |
| 13.1 Expected and Measured for DY WW $W+jets$, $t\bar{t}$ control regions and signal regions. | 133 |
| 13.2 Expected and Measured for DY WZ $W+jets$, $t\bar{t}$ tag and untag control regions. | 134 |
| 13.3 Expected and Measured for DY WZ $W+jets$, $t\bar{t}$ tag and untag signal regions. | 135 |
| 13.4 Expected and Measured for VBF WW $W+jets$, $t\bar{t}$ control regions and signal regions. | 136 |
| 13.5 Expected and Measured for VBF WZ $W+jets$, $t\bar{t}$ control regions and signal regions. | 137 |
| 13.6 Fitted background normalizations for $t\bar{t}$ and $W+jets$ backgrounds for the DY WW analysis region. | 138 |
| 13.7 Fitted background normalizations for $t\bar{t}$ and $W+jets$ backgrounds for the DY WZ analysis region. | 138 |
| 13.8 Fitted background normalizations for $t\bar{t}$ and $W+jets$ backgrounds for the VBF WW analysis region. | 138 |
| 13.9 Fitted background normalizations for $t\bar{t}$ and $W+jets$ backgrounds for the VBF WZ analysis region. | 139 |

14.1 This table shows the best fit slope and intercept for the 2-d distribution of number of tracks vs. jet $\ln(p_T)$ for the leading jet in the background and HVT Z' samples. The tagging efficiency is shown for the 90% working point in the last column. The background jets contain more gluons than the signal jets. Consequently, the best fit line for the background predicts larger values of the number of tracks in jets for the background than the considered signals. . . . 162

Abstract

Search for WW and WZ Resonances in $\ell\nu qq$ final states in pp collisions at

$\sqrt{s} = 13$ TeV with the ATLAS detector

by

Natasha Woods

This thesis presents a search for WW and WZ resonances using data from pp collisions at $\sqrt{s} = 13$ TeV using the ATLAS detector, corresponding to an integrated luminosity of 139 fb^{-1} . Diboson resonances are predicted in a number of Standard Model (SM) extensions, such as Extended Gauge Models, and Extra dimensional models. This search looks for resonances where one W boson decays leptonically and the other W or Z boson decays hadronically. This search is sensitive to diboson resonance production via vector-boson fusion as well as quark-antiquark annihilation and gluon-gluon fusion mechanisms. No significant excess of events is observed with respect to the Standard Model backgrounds, and constraints on the masses of new W' , Z' , and bulk-RS Gravitons are extended to up to 3.3 TeV, depending on the model. As the dominant backgrounds in this search contain gluons, classifying jets as quark-initiated or gluon-initiated would make this analysis more sensitive to new physics. Towards this end, this thesis provides a calibrated quark-gluon tagger based on the multiplicity of charged particles within a jet.

Introduction

³ Chapter 1

⁴ Introduction

⁵ In general, humanity has continually strived to understand the structure and
⁶ dynamics of reality for widely varying reasons. Each academic field uses a spe-
⁷ cific set of concepts and models to describe nature. Physics is one such field,
⁸ that uses mathematical objects to systematically develop testable models about
⁹ the universe. Currently, the most fundamental types particles are fermions and
¹⁰ bosons. Fermions are the particles that make up the "ordinary" matter of the
¹¹ universe, while bosons are the quanta of the fundamental forces. The Standard
¹² Model (SM) of particle physics describes the quantum behavior of three of the
¹³ four fundamental forces: electromagnetic, strong, and weak forces.

¹⁴ The Standard Model has consistently described much of reality to an extreme
¹⁵ degree of accuracy. It has predicted cross sections for strong and electroweak
¹⁶ processes that span over ten orders of magnitude [see Fig. 3.1] and contains no
¹⁷ known logical inconsistencies. Despite the reality of the Standard Model, it still
¹⁸ fails to describe aspects of reality and suffers from aesthetic issues. The SM fails
¹⁹ to account for dark matter, dark energy, neutrino masses, the hierarchy of the
²⁰ fundamental force strengths, and other issues that may have not been noticed
²¹ yet! This incompleteness may indicate that a more fundamental theory exists. It

22 is hoped that such a theory would address the aforementioned phenomena and
23 the ad-hoc structure and parameter values of the SM. In particular the relative
24 scales of the fundamental forces impose oddly fine-tuned SM parameters, unless
25 there is additional structure at higher energies (e.g. between the electroweak and
26 Planck scales). This and other theoretical arguments motivate the search for new
27 physics at the TeV scale. The set of theories that hope to explain more of reality
28 are known as Beyond the Standard Model theories (BSM). Many of these theories,
29 if true, would revolutionize concepts of symmetry and space-time, which would
30 be intrinsically meaningful.

31 To probe the physics at this high energy frontier, physicists often collide ener-
32 getic particles that combine to produce massive particles, such as the Higgs boson
33 and top quark. The more energetic the colliding particles are the more massive
34 produced particles can be. Currently, the world's highest energy particle collider
35 is the Large Hadron Collider (LHC) at the European Organization for Nuclear
36 Research (CERN).

37 This thesis presents a search for WW and WZ resonances using data from pp
38 collisions at $\sqrt{s} = 13$ TeV using the ATLAS detector at CERN, corresponding
39 to an integrated luminosity of 139 fb^{-1} . Diboson resonances are predicted in a
40 number of BSM theories, such as Extended Gauge Models and Extra dimensional
41 models. This search looks for resonances where one W boson decays leptonically
42 and the other W or Z boson decays hadronically. This search is sensitive to
43 diboson resonance production via vector-boson fusion as well as quark-antiquark
44 annihilation and gluon-gluon fusion mechanisms (which will be collectively called
45 non-VBF modes).

46 To search for these new resonances, Monte-Carlo simulations are used to model
47 SM backgrounds and BSM signals. In these simulations, a series of optimized cuts

48 are used to create signal regions (SR) to identify the leptonic and hadronic decay
49 products of the resonance, maximize signal acceptance, and minimize background
50 contamination. In these regions, the resonance mass is calculated as the combined
51 system mass of the leptonic and hadronic system. The expected resonance mass
52 distribution from the simulated backgrounds and anticipated signal are compared
53 to data to search for the existence of these BSM signals (also known as a "bump
54 hunt"). Control regions enriched in the dominant backgrounds, $t\bar{t}$ and $W+\text{jets}$
55 (TCR and WCR, respectively) are constructed to be orthogonal to SRs and used
56 to determine the normalization of the $t\bar{t}$ and $W+\text{jets}$ backgrounds in SRs.

57 The VBF W' and Z' and ggF W' and Z' resonances studied have unique
58 SR and CR selections to maximize analysis sensitivity. RS Graviton signals are
59 probed using the same selections as the ggF Z' signal. Additionally, more mas-
60 sive resonances are more likely to have boosted W/Z bosons. As the boost of
61 the hadronically decaying boson increases the separation of its hadronic decay
62 products decreases. When the hadronically decaying boson has sufficient boost,
63 the two quarks will overlap and not be identified separately. For this reason, a
64 set of "resolved" selections are used when the hadronic decay products are recon-
65 structed separately, and "merged" selections when the decay products overlap and
66 identified as a single object in the event. A W/Z tagger identifies merged jets as
67 originating from a W/Z bosons based on jet substructure and mass cuts. However,
68 the more boosted the jet is the less likely it is to pass the jet substructure cut, due
69 to track merging. Consequently, the merged selection uses a high purity region
70 (HP), which requires that the jet pass both cuts, and low purity (LP) region where
71 the jet can fail the jet substructure cut.

72 The aforementioned SR definitions veto events with b -jets to minimize $t\bar{t}$ con-
73 tamination. However, b -jets are anticipated from W' resonances from the hadron-

74 ically decaying Z boson. To increase the signal acceptance of these resonances,
75 a $Z \rightarrow bb$ tagger is used to construct additional SR and CRs called the "tagged"
76 regions (and "un>tagged" if the event fails the $Z \rightarrow bb$ tagger).

77 For each signal model, the simulated and measured resonance mass distribu-
78 tions in the relevant SR and CRs are combined to construct a likelihood. This
79 likelihood is parameterized by the signal strength parameter, μ and systematic
80 uncertainties of the resonance mass distribution. This likelihood is used to quan-
81 tify the likelihood of a certain signal model given the anticipated backgrounds and
82 measured data.

83 No significant excess of events is observed with respect to the Standard Model
84 backgrounds, and constraints on the masses of new W' , Z' , and bulk-RS Gravi-
85 tons are extended to up to 3.3 TeV, depending on the model. As the dominant
86 backgrounds in this search contain gluons, classifying jets as quark-initiated or
87 gluon-initiated would improve the sensitivity of this analysis to new physics. To-
88 wards this end, this thesis provides a calibrated quark-gluon tagger based on the
89 multiplicity of charged particles within a jet.

90 Part II reviews the SM, its successes and shortcomings, and the aforemen-
91 tioned BSM theories that address the incompleteness of the SM. The structure
92 and performance of the ATLAS detector used is given in Part III. Part IV summa-
93 rizes the search for the diboson resonances using ATLAS data from pp collisions
94 at $\sqrt{s} = 13$ TeV. Finally, Part V examines the prospects for a quark gluon tagger
95 based on the track multiplicity of jets and details the calibration of this tagger.

Part II

Theoretical Motivation

97

₉₈ **Chapter 2**

₉₉ **The Standard Model of Particle**

₁₀₀ **Physics**

₁₀₁ **2.1 Introduction**

₁₀₂ By determining the dynamics of the most elementary degrees of freedom, par-
₁₀₃ ticle physics hopes to uncover the fundamental laws of the universe. The definition
₁₀₄ of elementary has evolved through time and currently refers to matter and force
₁₀₅ mediating particles: fermions and bosons, respectively. The Standard Model of
₁₀₆ Particle Physics (SM) describes the quantum behavior of three of the four funda-
₁₀₇ mental forces: weak, strong, and electromagnetic, via boson and fermion interac-
₁₀₈ tions. Gravity is not included in the SM and still under investigation.

₁₀₉ **2.2 Quantum Field Theory**

₁₁₀ In the SM, forces (and particles) are represented as fields. In this context,
₁₁₁ fields are mathematical objects that define a tensor (e.g. scalar, vector, etc) at
₁₁₂ every point on a manifold, here the manifold is space-time. These fields obey laws

₁₁₃ dictated by Quantum Field Theory (QFT). Particles arise naturally in QFT as
₁₁₄ quantized field excitations localized in spacetime.

₁₁₅ According to Noether's theorem, symmetries of a field give rise to conserved
₁₁₆ quantities (e.g. time-translation invariance leads to energy conservation). Often
₁₁₇ in the history of physics, a conserved quantity of a field is found and then the
₁₁₈ underlying symmetry of the field is inferred. Gauge symmetries are symmetries
₁₁₉ among the internal degrees of freedom of the field (components of the tensor),
₁₂₀ which give rise to quantities associated with fields. By specifying the symmetries
₁₂₁ of a system the dynamics and conserved quantities of the system may be succinctly
₁₂₂ defined.

₁₂₃ 2.3 $U(1)_{EM}$ Local Gauge Invariance

₁₂₄ The Lagrangian of Quantum Electrodynamics (QED) describes the electro-
₁₂₅ magnetic force. QED may be derived by requiring local $U(1)_{EM}$ gauge invariance
₁₂₆ of the free dirac fermion Lagrangian, ψ :

$$\mathcal{L} = i\bar{\psi}\gamma^\mu\partial_\mu\psi - m\bar{\psi}\psi \quad (2.1)$$

₁₂₇ This symmetry may be represented as a complex number with unit modulus,
₁₂₈ $e^{i\theta}$. $U(1)$ gauge invariance requires this gauge transformation of ψ will leave the
₁₂₉ Lagrangian unchanged.

$$\psi(x) \rightarrow \psi'(x) = e^{i\theta(x)}\psi(x) \quad (2.2)$$

₁₃₀ NB: This transformation is a local gauge transformation as θ depends on the
₁₃₁ spacetime coordinate.

₁₃₂ By requiring this symmetry of the free Dirac fermion Lagrangian:

$$\mathcal{L} = i\bar{\psi}\gamma^\mu\partial_\mu\psi - m\bar{\psi}\psi \quad (2.3)$$

¹³³ The mass term is unaffected, but the kinetic term is modified due to $\theta(x)$.

$$\mathcal{L} \rightarrow \mathcal{L}' = i\bar{\psi}e^{-i\theta(x)}\gamma^\mu\partial_\mu\psi e^{i\theta(x)} - m\bar{\psi}e^{-i\theta(x)}\psi e^{i\theta(x)} \quad (2.4)$$

¹³⁴

$$= i\bar{\psi}\gamma^\mu(\partial_\mu\psi + i\psi\partial_\mu\theta) - m\bar{\psi}\psi \quad (2.5)$$

¹³⁵ The $\partial_\mu\theta$ terms breaks the gauge invariance of the Lagrangian. By introducing a
¹³⁶ new field, A_μ we can recover the gauge invariance of the derivative. Now redefining
¹³⁷ the derivative as the covariant derivative:

$$D_\mu\psi \equiv (\partial_\mu - iqA_\mu)\psi \quad (2.6)$$

¹³⁸ And letting A_μ transform under $U(1)$ as:

$$A_\mu \rightarrow A_\mu + \delta A_\mu \quad (2.7)$$

¹³⁹ The transformed covariant derivative becomes:

$$D_\mu\psi \rightarrow D_\mu\psi' = (\partial_\mu - iqA_\mu)\psi' \quad (2.8)$$

¹⁴⁰

$$= (\partial_\mu - iq(A_\mu + \delta A_\mu))\psi e^{i\theta} \quad (2.9)$$

¹⁴¹

$$= e^{i\theta}D_\mu + ie^{i\theta}\psi(\partial_\mu\theta - q\delta A_\mu) \quad (2.10)$$

¹⁴² The covariant derivative can be made gauage invariant by setting the last term
¹⁴³ to zero.

$$\delta A_\mu = \frac{1}{q} \partial_\mu \theta \quad (2.11)$$

¹⁴⁴ So now A_μ transforms as:

$$A_\mu \rightarrow A_\mu + \frac{1}{q} \partial_\mu \theta \quad (2.12)$$

¹⁴⁵ Finally, replacing the derivative with the covariant derivative the Dirac La-
¹⁴⁶ grangian we have:

$$\mathcal{L} = i\bar{\psi}\gamma^\mu D_\mu \psi - m\bar{\psi}\psi - \frac{1}{4}F_{\mu\nu}F^{\mu\nu} \quad (2.13)$$

¹⁴⁷

$$= \mathcal{L}_{QED} \quad (2.14)$$

¹⁴⁸ Here $F_{\mu\nu} \equiv \partial_\mu A_\nu - \partial_\nu A_\mu$. This last term in the Lagrangian is the kinetic
¹⁴⁹ energy of the gauge boson field.

¹⁵⁰ So we have derived the QED Lagrangian. By requiring the free Dirac La-
¹⁵¹ grangian to be invariant under local U(1) transformations we have generated a
¹⁵² new gauge boson field, A_μ , which describes the photon. As expected the photon
¹⁵³ interacts with fermions.

¹⁵⁴ Stepping back, a global U(1) gauge symmetry of the free Dirac Lagrangian
¹⁵⁵ implies we cannot measure the absolute phase of a charged particle. A local U(1)
¹⁵⁶ gauge symmetry changes the phase of fields differently across space time. For this
¹⁵⁷ type of transformation to leave the Lagrangian invariant, we had to introduce an
¹⁵⁸ additional field, A_μ , which "communicates" these phase changes across space-time.
¹⁵⁹ In less formal language this effectively means: if the field at one location changes,
¹⁶⁰ this change is conferred to other particles via A_μ .

¹⁶¹ 2.4 Yang-Mills Gauge Theories

¹⁶² Requiring $U(1)_{EM}$ gauge invariance of the free Dirac Lagrangian gave us QED.

¹⁶³ Requiring different gauge symmetries we can derive the structure of other inter-

¹⁶⁴ actions. Any gauge symmetry may be written as:

$$\psi_i \rightarrow \exp(i\theta^a T_{ij}^a) \psi_j \quad (2.15)$$

¹⁶⁵ Here θ is a dimensionless real parameter and T is the generator of the gauge

¹⁶⁶ symmetry group. With this the covariant derivative can be written as:

$$D_\mu \psi_i \equiv \partial_\mu \psi_i + ig A_\mu^a T_{ij}^a \psi_j \quad (2.16)$$

¹⁶⁷ Then the gauge field must transform as:

$$A_\mu^a \rightarrow A_\mu^a - \frac{1}{g} \partial_\mu \theta^a - f^{abc} \theta^b A_\mu^c \quad (2.17)$$

¹⁶⁸ Here f is the structure constant of the gauge group. The field strength tensor

¹⁶⁹ is given by:

$$F_{\mu\nu}^a \equiv \partial_\mu A_\nu^a - \partial_\nu A_\mu^a - g f^{abc} A_\mu^b A_\nu^c \quad (2.18)$$

¹⁷⁰

$$F_{\mu\nu}^a \rightarrow F_{\mu\nu}^a - f^{abc} \theta^b F_{\mu\nu}^c \quad (2.19)$$

¹⁷¹ This gives the Yang-Mills Lagrangian:

$$\mathcal{L}_{YM} = -\frac{1}{4} F_{\mu\nu}^{a\mu\nu} F_{\mu\nu}^a + i \bar{\psi}_i \gamma^\mu D_\mu \psi_i + m \bar{\psi}_i \psi_i \quad (2.20)$$

¹⁷² 2.5 Particles in the Standard Model

¹⁷³ The SM consists of fermions (half-integer spin matter constituents) and bosons
¹⁷⁴ (integer spin force mediators). Fermions are spinor representations of the Poincare
¹⁷⁵ group and can be further separated into leptons and quarks. Bosons are the result
¹⁷⁶ of requiring a particular symmetry among the spinor fields:

$$SU(3)_C \times SU(2)_L \times U(1)_Y \quad (2.21)$$

¹⁷⁷ $SU(3)_C$ is the symmetry group of the strong force and generates eight gluon
¹⁷⁸ fields, G_μ . $SU(2)_L$ is the symmetry group of the Electroweak force and generates
¹⁷⁹ three electroweak boson fields. The mixing of this $SU(2)_L$ and $U(1)_Y$ gives rise
¹⁸⁰ to the photon field, where Y is the weak-hypercharge:

$$Y = 2(Q - T_3) \quad (2.22)$$

¹⁸¹ Q is the electromagnetic charge, and T_3 is the z-component of the weak isospin.
¹⁸² Weak isospin is the charge associated with the $SU(2)_L$ symmetry. The correspond-
¹⁸³ ing covariant derivative is then:

$$D_\mu \phi \equiv (\partial_\mu + ig_1 B_\mu Y_{L/R} + [ig_2 W_\mu^\alpha T^\alpha]_L + [ig_3 G_\mu^\alpha \tau^\alpha]_C) \psi \quad (2.23)$$

¹⁸⁴ It is important to note that the gauge symmetry of the SM yields a particular
¹⁸⁵ structure of the fermion representations. So for a given fermion to interact with
¹⁸⁶ a given gauge field it must have a non-zero corresponding Noether charge for
¹⁸⁷ that gauge symmetry. If the corresponding Noether charge is zero, that fermion
¹⁸⁸ transforms as a singlet and does not participate in that gauge interaction.

¹⁸⁹ Fermions are divided into quarks and leptons based on their transformations
¹⁹⁰ under $SU(3)_C$. Quarks transform as color triplets. Leptons transform as color

singlets and consequently do not interact with gluons. Fermions may be further
 classified by their $SU(2)_L$ interactions. Only the left-chiral part of fermions (denoted by L here) transform as $SU(2)_L$ doublets, the right-chiral part forms singlets under this gauge. Lastly, all these groups of particles come in three generations, each a heavier copy of the previous, but with differing flavor quantum numbers.
 This is summarized in Table 2.1 and shown in Figures 2.1 and 2.2.

| SM Fermion Gauge Group | First Generation | Second Generation | Third Generation | $(SU(3)_C, SU(2)_L, U(1)_Y)$ Representations |
|------------------------|--|--|--|---|
| Left-handed quarks | $\begin{pmatrix} u_L^r & u_L^g & u_L^b \\ d_L^r & d_L^g & d_L^b \end{pmatrix}$ | $\begin{pmatrix} c_L^r & c_L^g & c_L^b \\ s_L^r & s_L^g & s_L^b \end{pmatrix}$ | $\begin{pmatrix} t_L^r & t_L^g & t_L^b \\ b_L^r & b_L^g & b_L^b \end{pmatrix}$ | $(3, 2, \frac{1}{6})$ |
| Right-handed quarks | (u_R^r, u_R^g, u_R^b) (d_R^r, d_R^g, d_R^b) | (c_R^r, c_R^g, c_R^b) (s_R^r, s_R^g, s_R^b) | (t_R^r, t_R^g, t_R^b) (b_R^r, b_R^g, b_R^b) | $(3, 1, \frac{2}{3})$ $(3, 1, -\frac{1}{3})$ |
| Left-handed leptons | $\begin{pmatrix} \nu_e^L \\ e_L \end{pmatrix}$ | $\begin{pmatrix} \mu_e^L \\ \mu_L \end{pmatrix}$ | $\begin{pmatrix} \tau_e^L \\ \tau_L \end{pmatrix}$ | $(1, 2, -\frac{1}{2})$ |
| Right-handed leptons | e_R | μ_R | τ_R | $(1, 1, -1)$ |

Table 2.1: Representations of the SM fermions under $SU(3)_C \times SU(2)_L \times U(1)_Y$ gauge symmetry group. Rows are correspond to different weak isospin states and columns to different QCD color states.

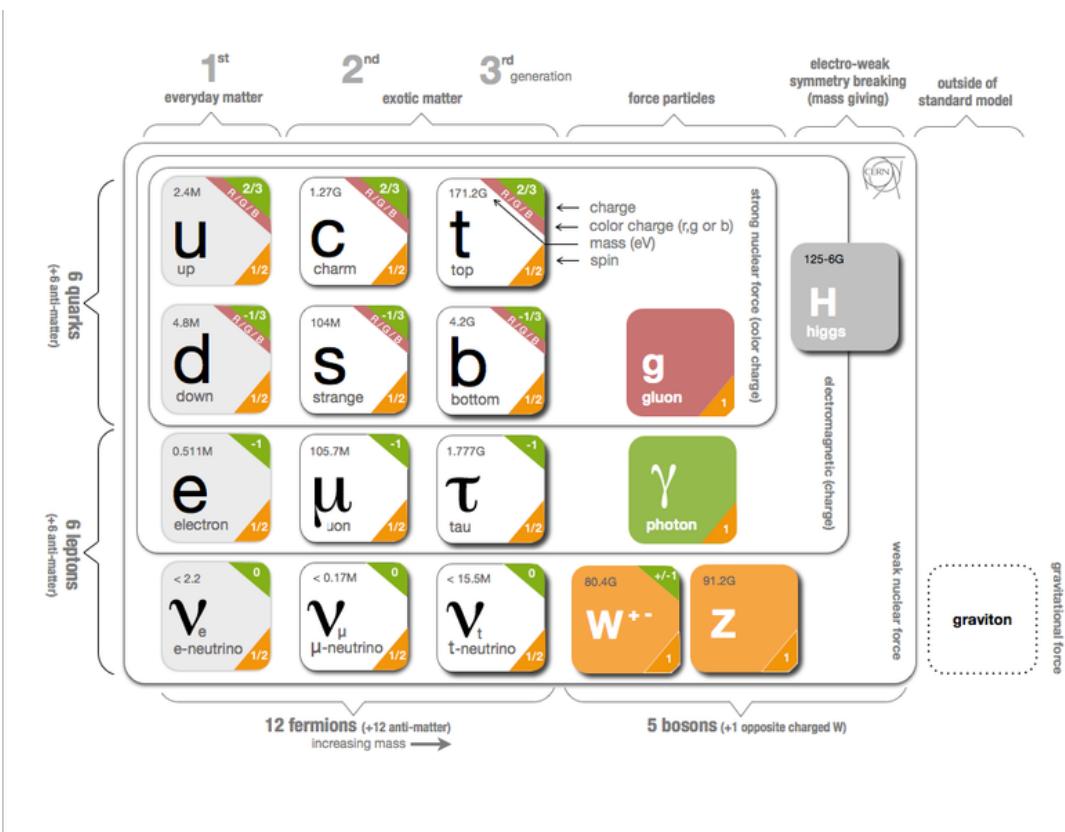

Figure 2.1: The particles of the Standard Model.

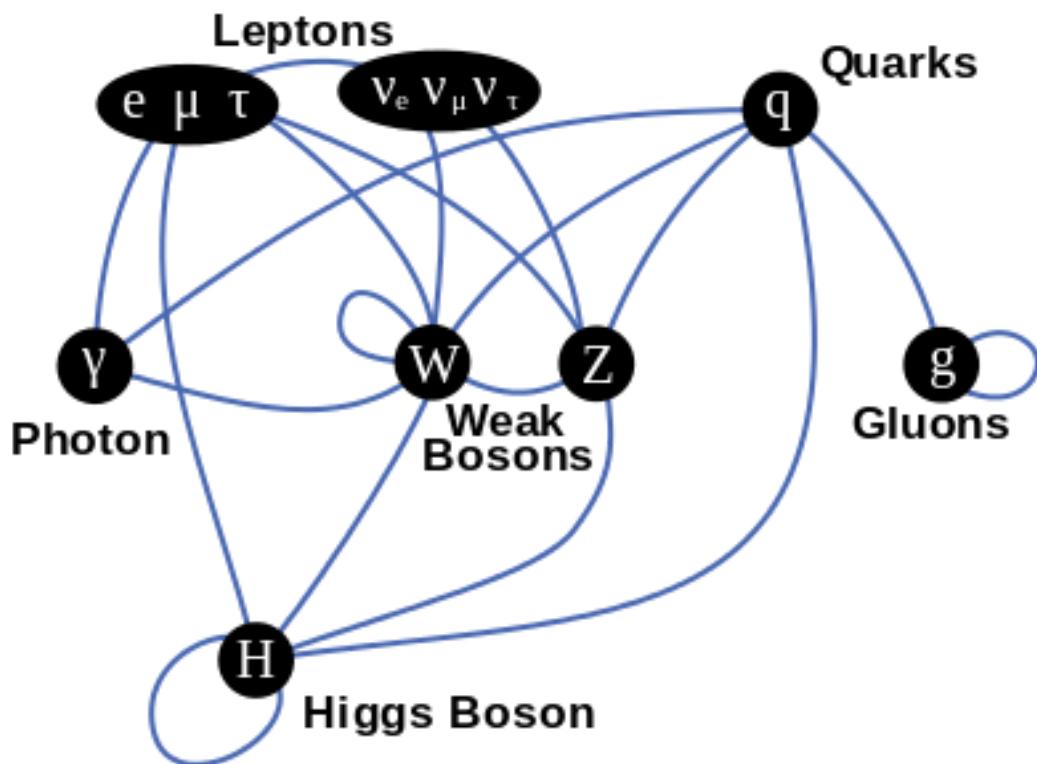

Figure 2.2: Summary of how Standard Model particles interact with other Standard Model particles.

197 Now we can understand the SM Lagrangian density as a Yang-Mills theory
 198 with the gauge group: $SU(3)_C \times SU(2)_L \times U(1)_Y$ with an additional $SU(2)$ complex
 199 scalar Higgs field doublet that will be discussed later.

$$\begin{aligned} \mathcal{L}_{SM} = & \underbrace{-\frac{1}{4}B_{\mu\nu}B^{\mu\nu} - \frac{1}{4}W_{\mu\nu}^a W^{a\mu\nu} - \frac{1}{4}G_{\mu\nu}^\alpha G^{\alpha\mu\nu}}_{\text{Kinetic Energies and Self-Interactions of Gauge Bosons}} \\ & + \underbrace{\bar{L}_i \gamma^\mu (i\partial_\mu - \frac{1}{2}g_1 Y_{iL} B_\mu - \frac{1}{2}g_2 \sigma^a W_\mu^a) L_i}_{\text{Kinetic Energies and EW Interactions of Left-handed Fermions}} \\ & + \underbrace{\bar{R}_i \gamma^\mu (i\partial_\mu - \frac{1}{2}g_1 Y_{iR} B_\mu) R_i}_{\text{Kinetic Energies and EW Interactions of Right-Handed Fermions}} \\ & + \underbrace{\frac{ig_3}{2} \bar{Q}_j \gamma^\mu \lambda^\alpha G_\mu^\alpha Q_j}_{\text{Strong Interactions between Quarks and Gluons}} \\ & + \underbrace{\frac{1}{2} |(i\partial_\mu - \frac{1}{2}g_1 B_\mu - \frac{1}{2}g_2 \sigma^a W_\mu^a)\Phi|^2 - V(\Phi)}_{\text{Electroweak Boson Masses and Higgs Couplings}} \\ & - \underbrace{(y_{kl}^d \bar{L}_k \Phi R_l + y_{kl}^u \bar{R}_k \tilde{\Phi} L_l + h.c.)}_{\text{Fermion Mass terms and Higgs Couplings}} \end{aligned}$$

200 Here several abstract spaces are being spanned:

- 201 – a spans the three $SU(2)_L$ gauge fields with generators expanded in Pauli
 202 matrices, $T^\alpha = \frac{1}{2}\sigma^\alpha$
- 203 – α spans the eight $SU(3)_C$ gauge fields, with generators expanded in Gell-
 204 Mann matrices, $\tau^\alpha = \frac{1}{2}\lambda^\alpha$
- 205 – L/R represent left and right projections of Dirac fermion fields. The Strong
 206 interaction is not chiral, so $Q = L+R$

- 207 – μ and ν are four-vector indices
- 208 – i, j, k are summed over the three generations of SM particles.

209 2.6 Higgs Mechanism

210 The SM Lagrangian without the addition of a Higgs field does not allow for
211 gauge boson and fermion mass terms: $\frac{1}{2}m_A^2 A_\mu A_\mu$ and $m(\bar{\psi}\psi)$, as these terms are
212 not gauge invariant. By introducing the Higgs field, mass terms for these particles
213 may be included in a gauge invariant way. This field is a complex doublet with a
214 potential $V(\Phi)$:

$$\Psi = \begin{pmatrix} \Phi^\dagger \\ \Phi^0 \end{pmatrix} \quad (2.24)$$

215 $V(\Phi) = \mu^2 \Phi^\dagger \Phi + \lambda |\Phi^\dagger \Phi|^2 \quad (2.25)$

216 The minima of this field occurs for $|\Phi| = \sqrt{\frac{\mu^2}{2\lambda}} \equiv \frac{v}{2}$. This yields degenerate
217 minima, this symmetry is broken by choosing a specific minima (a.k.a. sponta-
218 neous symmetry breaking). By convention $\Phi_{min} = \frac{1}{\sqrt{2}} \begin{pmatrix} 0 \\ v \end{pmatrix}$ is chosen. This means
219 the ground state of the Higgs field (Higgs vacuum) is non-zero, $\sqrt{\frac{-\mu^2}{\lambda}}$. The Higgs
220 Field may now be expanded around this new ground state:

$$\Phi(x) = \frac{1}{\sqrt{2}} \begin{pmatrix} 0 \\ v + h(x) \end{pmatrix} \quad (2.26)$$

221 This non-zero Higgs vacuum now generates mass terms for the gauge bosons
222 from the following term in the Lagrangian:

$$|(-\frac{1}{2}g_1B_\mu - \frac{1}{2}g_2\sigma^aW_\mu^a)\Phi|^2 = \frac{1}{2}m_W^2W_\mu^+W^{-\mu} + \frac{1}{2}m_Z^2Z_\mu Z^\mu \quad (2.27)$$

223 where:

$$W_\mu^\pm \equiv \frac{1}{\sqrt{2}}(W_\mu^1 \mp iW_\mu^2) \quad (2.28)$$

$$\begin{aligned} \text{224} \quad Z_\mu &\equiv \frac{1}{\sqrt{g_1^2 + g_2^2}}(g_2W_\mu^2 - g_1B_\mu) \end{aligned} \quad (2.29)$$

$$\begin{aligned} \text{225} \quad m_W &= \frac{vg_2}{\sqrt{2}} \end{aligned} \quad (2.30)$$

$$\begin{aligned} \text{226} \quad m_Z &= \frac{v}{\sqrt{2}}\sqrt{g_1^2 + g_2^2} \end{aligned} \quad (2.31)$$

227 The Higgs field also generates a mass term for the Higgs boson and self-
228 interactions for the Higgs boson.

229 2.7 Electroweak Theory

230 $SU(2)_L$ generates W^\pm, W^0 gauge bosons, which would be massless if $SU(2)_L$
231 was a perfect symmetry. These bosons are massive as this symmetry is broken.

232 The mass eigenstates, Z and γ given by:

$$\begin{pmatrix} Z_\mu \\ A_\mu \end{pmatrix} = \begin{pmatrix} \cos\theta_W & -\sin\theta_W \\ \sin\theta_W & \cos\theta_W \end{pmatrix} \begin{pmatrix} W_\mu^3 \\ B_\mu \end{pmatrix} \quad (2.32)$$

233 Here θ_W is the Weinberg angle given by:

$$\cos\theta_W = \frac{g_2}{\sqrt{g_1^2 + g_2^2}} = \frac{m_W}{m_Z} \quad (2.33)$$

²³⁴ 2.8 Quantum ChromoDynamics

²³⁵ As mentioned earlier the Strong Force, which binds the proton together, is
²³⁶ mediated by gluons. Quantum Chromodynamics is the QFT which describes the
²³⁷ interactions of quarks and gluons via $SU(3)_C$ symmetry. QCD contains features
²³⁸ not present in Electroweak Interactions due to $SU(3)_C$ generators not commuting
²³⁹ (a.k.a. $SU(3)_C$ is a non-abelian group) and the number of quark flavors (n_f).
²⁴⁰ For example, in QCD there is color confinement and asymptotic freedom due to
²⁴¹ the structure constants being non-zero. Requiring $SU(3)_C$ local gauge invariance
²⁴² implies:

$$\psi(x) \rightarrow \psi(x)' = \exp[i g_S \alpha(x) \cdot \hat{T}] \psi(x) \quad (2.34)$$

²⁴³ where $\alpha(x)$ is the local phase function, g_S is the strong coupling constant, and
²⁴⁴ \hat{T} are the eight generators of $SU(3)$ (note $\hat{T}^a = \frac{1}{2}\lambda^a a$, where λ^a are the Gell-Mann
²⁴⁵ matrices). As the Gell-Mann matrices are 3x3, this means ψ has three degrees of
²⁴⁶ freedom under these $SU(3)$ rotations. So we represent ψ under $SU(3)$ rotations
²⁴⁷ as:

$$\psi = \begin{pmatrix} \psi_{red} \\ \psi_{green} \\ \psi_{blue} \end{pmatrix} \quad (2.35)$$

²⁴⁸ Consequently, particle fields transforming under $SU(3)$ rotations have three
²⁴⁹ components which physicists describe as color components (red, green, and blue).
²⁵⁰ A particle's corresponding antiparticle has the corresponding anticolor. This color
²⁵¹ is the "charge" of QCD and is conserved under $SU(3)$ rotations. Combining colors,
²⁵² color neutral states (e.g. red and antired, or red, green and blue) may be created.
²⁵³ For the Free Dirac Lagrangian to remain invariant under $SU(3)$ transformations,

254 we must again postulate a boson field that modifies the derivative. The gluon
255 field tensor is given by ($\alpha = 1, \dots, 8$):

$$G_{\mu\nu}^k = \partial^\mu G_\alpha^\nu - \partial^\nu G_\alpha^\mu - g_S f^{\alpha\beta\gamma} G_\beta^\mu G_\gamma^\nu \quad (2.36)$$

256 Here $f^{\alpha\beta\gamma}$ are the structure constants of $SU(3)$. Combining all this gives the
257 QCD Lagrangian:

$$\mathcal{L}_{QCD} = \bar{\psi}_q i\gamma^\mu (D_\mu)_{ij} \psi^{qj} - m \bar{\psi}_q \psi_q - \frac{1}{4} G_{\mu\nu}^\alpha G^{\alpha\mu\nu} \quad (2.37)$$

258 Here i are the color indices, and q are the quark flavors. It is important to
259 note that quarks transform under the fundamental representation of $SU(3)$, while
260 gluons transform under the adjoint representation. This means quarks carry a
261 single color charge (red, green, blue, antired, antigreen, antiblue) and gluons carry
262 a color and anticolor charge.

263 Figure 2.3 shows the three dominant QCD interactions. Since gluons carry
264 color charge, they interact with one another. This does not occur in QED, as
265 photons do not have electric charge and therefore do not interact with each other.
266 In QED, a bare electron's effective charge is largest closest to the electron and
267 decreases as a function of distance. This is because the QED vacuum fills with
268 particle antiparticle pairs spontaneously, which screen the charge of the bare elec-
269 tron. The larger the distance from the electron, the smaller the effective charge
270 and therefore the weaker the force.

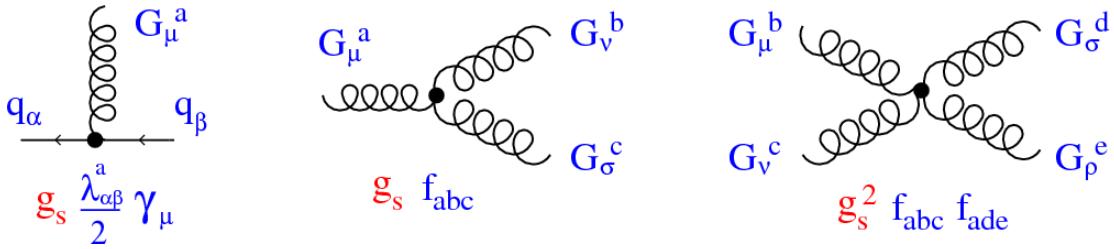

Figure 2.3: This figure shows the three dominant QCD interactions. From Ref. [18]

271 As the distance from a quark increases it's effective color charge increases due
 272 to the vacuum polarization in QCD. Color charge grows as the distance from
 273 the source increases (a.k.a. color is anti-screened in QCD). In this way, strong
 274 interactions become stronger at large distances (low momenta interactions). At
 275 small distances (large momenta interactions) strong interactions are significantly
 276 weaker and considered nearly free. This effect of referred to as asymptotic freedom.
 277 At large distances, a quark's effective charge is large and the strong force is more
 278 significant. This force becomes so strong that quarks form colorless bound states
 279 instead of remaining free particles. This effect is known as color confinement.
 280 This running of all SM fields is shown in Figure 2.4.

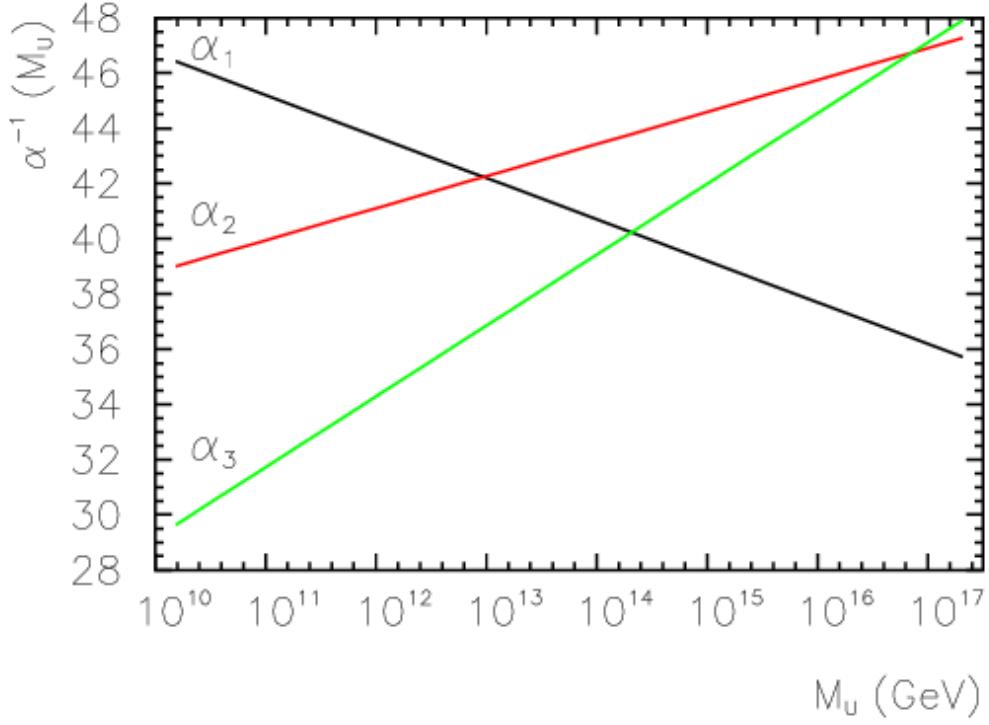

Figure 2.4: Strength of the U(1), SU(2), and SU(3) gauge couplings as a function of the energy scale of the interaction (Q). From Ref. [12]

Commonly the change in a particle's effective charge under a given force is quantified with $\beta(r) \equiv -\frac{de(r)}{d\ln r}$, where $e(r)$ is the effective charge of a given particle under a force. In QED this function is positive but in QCD this function is negative leading to confinement and asymptotic freedom. Moreover, one can calculate how the coupling (α) of a force varies with energies. (More deeply this amounts to incorporating renormalization and vacuum polarization in the boson propagators).

For QCD this is:

$$\alpha_s(Q^2) = \frac{\alpha_s(\mu^2)}{1 + \frac{\alpha_s(\mu^2)}{12\pi}(33 - 2n_f)\ln(Q^2/\mu^2)} \quad (2.38)$$

where Q is the momentum of the force is probed at, μ^2 is the renormaliza-

289 tion scale, n_f is the number of quark flavors. There are six quark flavors in SM
290 QCD, making $33 - 2n_f > 0$. This factor being positive and the $\ln(Q^2/\mu^2)$ being
291 in the denominator means that as Q^2 increases α_s decreases. So for large Q^2 , α_s
292 is small and SM QCD is asymptotically free, while for small Q^2 , α_s is large and
293 SM QCD is confined, as mentioned earlier.

294 As stated previously, quarks and gluons have not been observed in isolation.
295 Instead they form bound colorless states. Hadronization is the process by which
296 quarks and gluons form hadrons. The process of hadronization is still an active
297 area of research. One qualitative description is show in Figure 2.5. In this figure,
298 as two quarks separate the color field between them is restricted to a tube with
299 energy density of $1\text{GeV}/\text{fm}$. As they separate further, the energy in the color field
300 increases, until there is enough energy to produce $q\bar{q}$ pairs, which breaks the color
301 field. This process repeats until quarks and antiquarks have low enough energy
302 to form colorless hadrons. The resulting spray of hadrons is called a jet.

303 Since quarks and gluons carry different color charges, their respective jets have
304 different properties. As quarks carry only a single color charge (vs. gluons which
305 have color and anticolor charge), so their jets have less constituent particles. More
306 precisely, the Altarelli-Parisi splitting functions [3] contain a factor C_A for gluon
307 radiation off a gluon and C_F for gluon radiation off a quark ($C_A/C_F = 9/4$). These
308 color factors are the prefactor in the Feynman diagrams for these processes [1],
309 which leads to gluon jets having more constituents and therefore more tracks than
310 quark jets. Gluon jets also tend to have a larger radius with lower momentum
311 constituents than quarks. There are many novel techniques to distinguish quarks
312 from gluons. For this study the number of charged particles will be focused on.

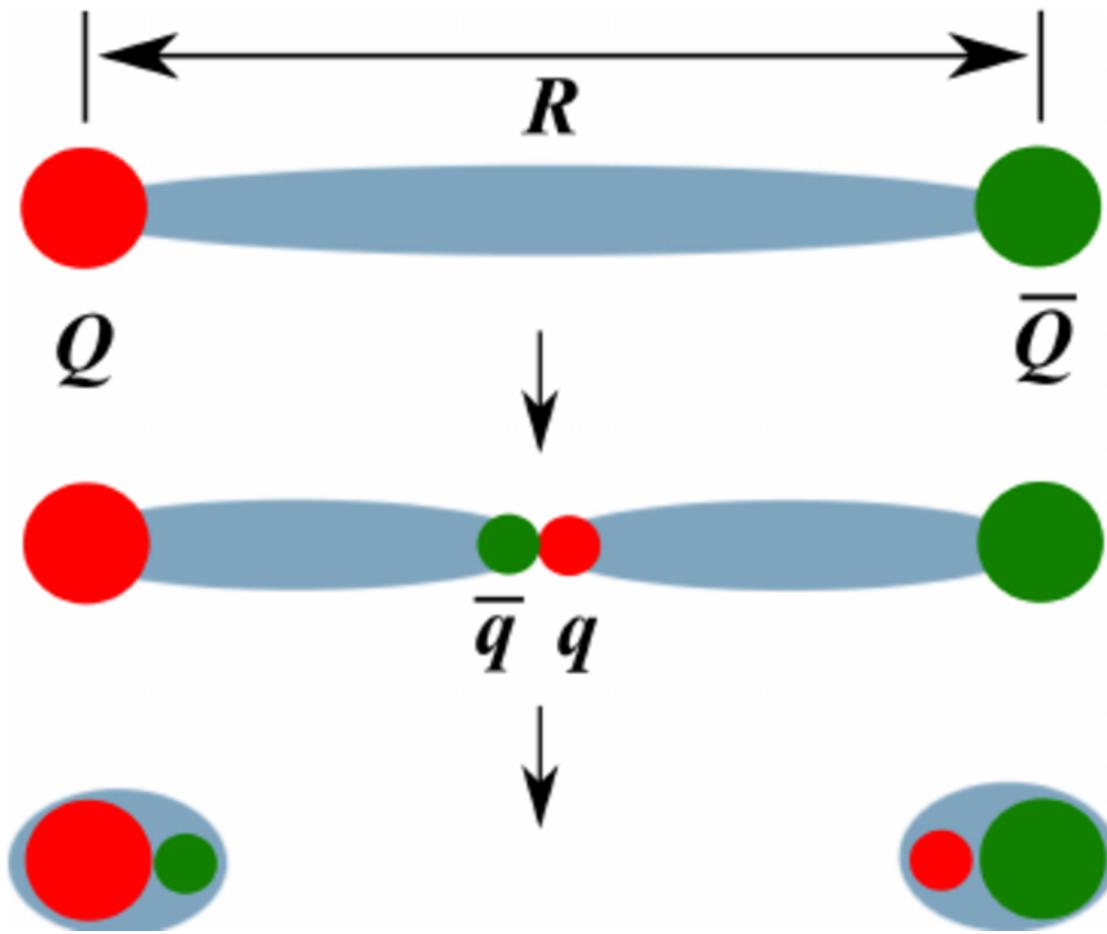

Figure 2.5: A cartoon of string breaking: the QCD string spanned between quark Q and antiquark \bar{Q} breaks due to $q\bar{q}$ creation [4]

³¹³ **Chapter 3**

³¹⁴ **Standard Model Successes and
Limitations**

³¹⁶ The Standard Model has accurately described most of the underlying principles
³¹⁷ of nature. It has predicted cross sections for strong and electroweak processes that
³¹⁸ span over ten orders of magnitude correctly [see Fig. 3.1] and contains no known
³¹⁹ logical inconsistencies. Despite the strength and reality of the Standard Model, it
³²⁰ still fails to describe some important aspects of reality and suffers from aesthetic
³²¹ issues. To date, dark matter and energy comprise 95% of the universe, but are
³²² not accounted for in the SM. Additionally, neutrinos are known to have mass but
³²³ are massless in the SM. There are mechanisms for introducing massive neutrinos
³²⁴ in the SM, but these mechanisms create hierarchy problems.

³²⁵ Possibly the most significant aesthetic issue is the hierarchy between the elec-
³²⁶ troweak and Planck scales. The electroweak scale is the scale of electroweak
³²⁷ symmetry breaking. The Planck scale is the scale where the gravitational force
³²⁸ is comparable in strength to the other forces. The Planck scale is where the SM
³²⁹ breaks down, as there is not an experimentally verified theory of quantum gravity,
³³⁰ and at this scale gravity cannot be ignored (like it can at the electro-weak scale).

331 These scales differ by ~ 30 orders of magnitude. Understanding the difference
332 in these energy scales may help explain the weakness of gravity at electroweak
333 scales, and possibly a QFT for gravity. (NB: This hierarchy can also be framed in
334 terms of the corrections to the Higgs mass, which depend on the UV cutoff scale -
335 where the SM is suppose to break, which is taken at the Planck scale. This leads
336 the quantum corrections to the Higgs mass that would force the Higgs mass to
337 $\sim 10^{18}$ TeV.)

338 These stark contrasts in scales may indicate that a more fundamental theory
339 exists. It is hoped that such a theory would explain and motivate some of the
340 ad-hoc features of the SM. In particular, the values of the 19 SM parameters (6
341 quark masses, 3 charged lepton masses, 3 gauge couplings, Higgs parameters (μ^2 ,
342 λ)), the structure of the fermion representations, etc.

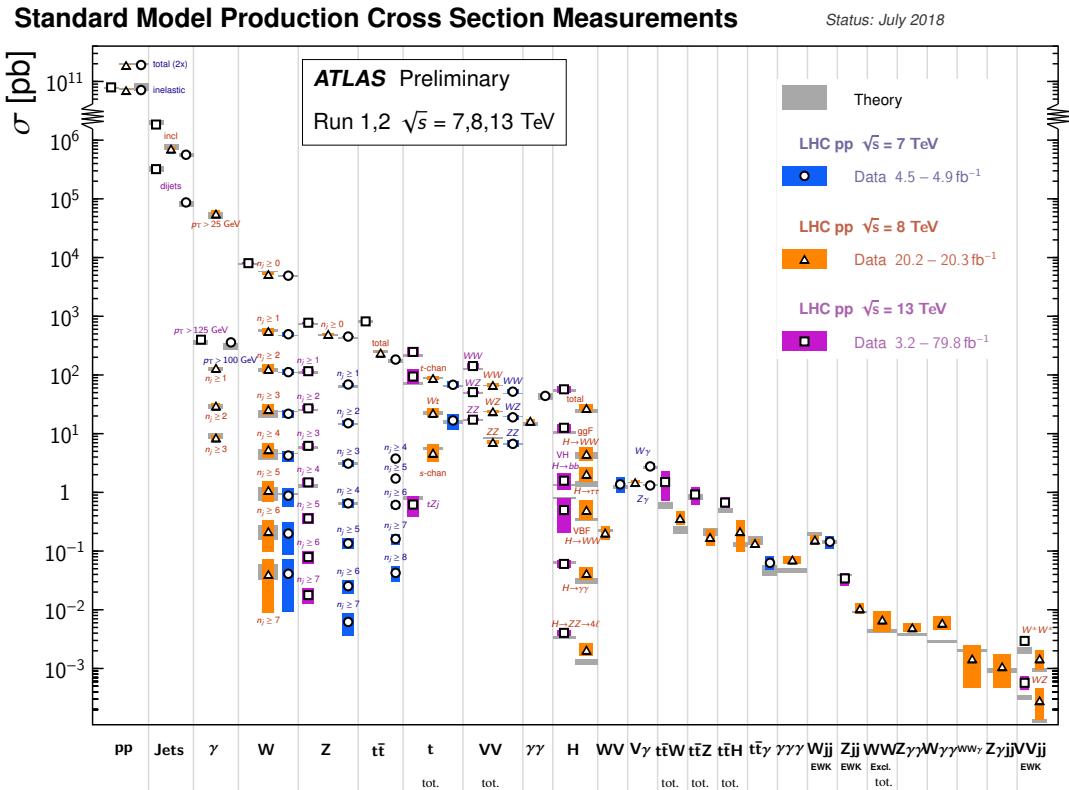

Figure 3.1: A comparison of cross section measurements at $\sqrt{s} = 7,8,13$ TeV from ATLAS compared to theoretical measurements. From Ref. [6]

³⁴³ **Chapter 4**

³⁴⁴ **New Physics Models with**
³⁴⁵ **Diboson Resonances**

³⁴⁶ **4.1 Randall Sundrum Bulk Model**

³⁴⁷ The electroweak-planck hierarchy may be explained by the existence of extra
³⁴⁸ dimensions, like the 5D Randall Sundrum Bulk Model ([19], [2]). In this model,
³⁴⁹ there is one extra warped spatial dimension, y , with a metric:

$$ds^2 = e^{-2k|y|} \eta_{\mu\nu} dx^\mu dx^\nu + dy^2 \quad (4.1)$$

³⁵⁰ where $e^{-k|y|}$ is the warp factor of the extra dimension, which is compactified on
³⁵¹ a S^1/Z_2 orbifold (a.k.a. a circle where $y \rightarrow -y$). This can be visualized as every
³⁵² point in space time having a line extending from it a distance L , representing
³⁵³ this fifth dimension. At the end of this line is the Planck brane. This fourth
³⁵⁴ spatial dimension separates two 4-D branes: Planck brane and TeV brane. We
³⁵⁵ live on the TeV brane, as shown in Figure 4.1. The Higgs field (and to a lesser
³⁵⁶ degree the top quark and graviton fields) is localized near the TeV Brane, while

357 the light fermion fields are localized more near the Planck brane. Fundamental
 358 parameters are set on the Planck brane. The warp factor may be scaled away from
 359 all dimensionless SM terms by field redefinitions. However, the only dimensionful
 360 parameter, $m_H^2 = v^2$ is rescaled by $\tilde{v} \sim e^{-kL} M_{Pl} \sim 1\text{TeV}$ for $kL \sim 35$, explaining
 361 why gravity is so weak on the TeV brane. Also, by localizing the light fermion
 362 fields near the Planck brane and top and graviton fields near the TeV brane, the
 363 light quarks will have smaller masses.

364 The two free parameters of this theory are M_{Pl} and k . Based on this RS Bulk
 365 model, all SM particles should have Kaluza-Klein (KK) excitations. In particular,
 366 the graviton would have KK excitations that prefer to decay to WW or ZZ, which
 367 is why this analysis searches for RS Gravitons.

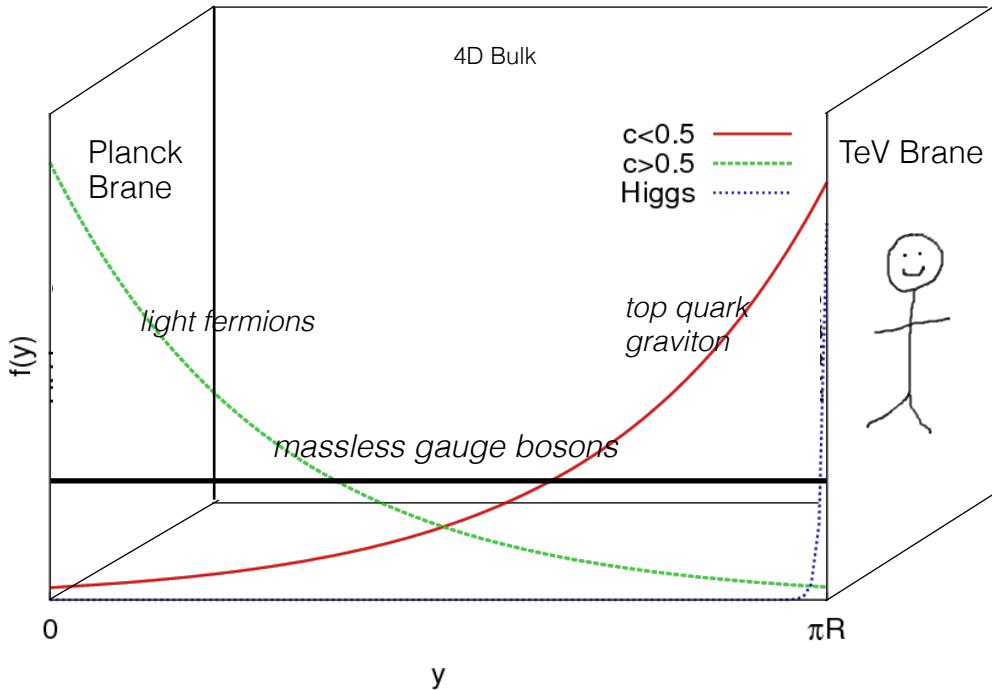

Figure 4.1: Cartoon of RS Bulk Model

368 4.2 Simple Standard Model Extensions

369 The RS Bulk model is motivated by resolving SM hierarchies, but it does not
370 address all of the other SM issues. There are many other interesting and well
371 motivated new physics frameworks that address these issues, but there is a lack
372 of completely predictive models, due to model flexibility (free parameters). It is
373 difficult for experimentalists to know which theories to search for in data. There-
374 fore, developing a model-independent resonance search that can be reinterperted
375 in the context of a given BSM theory is ideal.

376 This search is sensitive to the resonance mass and its interactions, but not
377 all of a given BSM model's parameters. Therefore, the BSM Lagrangian may be
378 reduced to only retain this information (mass parameters and couplings) following
379 the procedure in [17]. In this simplified approach, the new resonance searched for
380 is represented as an additional heavy vector triplet (HVT), which is a real vector
381 field in the adjoint representation of $SU(2)_L$ with vanishing hypercharge. This
382 results in one neutral and two charged bosons, defined as:

$$V^\pm = \frac{V_\mu^1 \mp i V_\mu^2}{\sqrt{2}} \quad (4.2)$$

$$V_\mu^0 = V_\mu^3 \quad (4.3)$$

384 The SM Lagrangian is then augmented with the additional terms:

$$\mathcal{L} \supset -\frac{1}{4} D_{[\mu} V_{\nu]}^a D^{[\mu} V^{\nu]}{}^a + \frac{m_V^2}{2} V_\mu^a V^{a\mu} + ig_V c_H V_\mu^a H^\dagger \tau^a \overset{\leftrightarrow}{D}{}^\mu H + \frac{g^2}{g_V} c_F V_\mu^a J_F^{\mu a} \quad (4.4)$$

385 In order the terms represent: the kinetic, V mass, Higgs- V interaction, and
386 V -left-handed fermion interaction terms. The g_V coupling factor determines the
387 coupling of the new resonance to left-handed fermions and the Higgs boson.

388 As benchmark models, this search considers resonances from extended gauge
389 symmetry (EGM) and composite Higgs models as discussed in [17] . The EGM
390 model predicts weakly coupled resonances, where $g_V = 1$, referred to later as
391 Model A. The composite Higgs Model is a strongly coupled model, where $g_V = 3$,
392 and later referred to as Model B. As shown in Eq. 4.4, the coupling of these
393 resonances to fermions scales as $g_f = g^2 c_F / g_V$, where g is the SM $SU(2)_L$ gauge
394 coupling and c_F is a free parameter. This then means that for Model B the
395 coupling to fermions is suppressed relative to Model A, leading to a smaller DY
396 production rate and branching ratio (BR) to fermionic final states. The coupling
397 of V to SM bosons scales as $g_H = g_V c_H$, where c_H is a free parameter on the
398 order of one for Model A and B. Consequently Model A resonances have a smaller
399 the BR to gauge bosons than Model B. For the pp collision data used, Model A
400 predicts larger production cross sections decaying to leptons and fermions than
401 Model B which decays primarily to gauge bosons.

402 Model A and B vectors are produced via quark-anti-quark annihilation and
403 the more rare vector-boson-fusion is considered by setting $g_H = 1$ and $g_F = 0$.
404 Both production modes are probed in this resonance search.

405 In summary, V couples most strongly to left-handed fermions and VV depen-
406 dent on g_V .

407

Part III

408

Experimental Setup

409 **Chapter 5**

410 **LHC**

411 The Large Hadron Collider (LHC) is the highest-energy particle collider in the
412 world. It was designed to expand the frontier of high energy particle collisions in
413 energy and luminosity. This enables LHC experiments to test the Standard Model
414 and search for new physics at higher energies than tested with previous colliders.
415 Collisions at higher energies not only produce more massive particles but also
416 more weakly interacting particles. Fig 5.1 shows production cross sections for
417 various processes at hadron colliders. The rate for electroweak physics processes
418 including W and Z scale with the center-of-momentum energy, \sqrt{s} .

419 The LHC consists of a 26.7 km (17 miles) ring, approximately 100 m un-
420 derground, outside Geneva, Switzerland. Counter-circulating proton (and occa-
421 sionally heavy ions) beams collide inside four experiments along the beam line:
422 ATLAS, CMS, LHCb, ALICE. ATLAS and CMS are general purpose detectors de-
423 signed to explore the high energy frontier. LHCb is designed to study the physics
424 of b -quarks. ALICE specializes in studying heavy ion collisions.

proton - (anti)proton cross sections

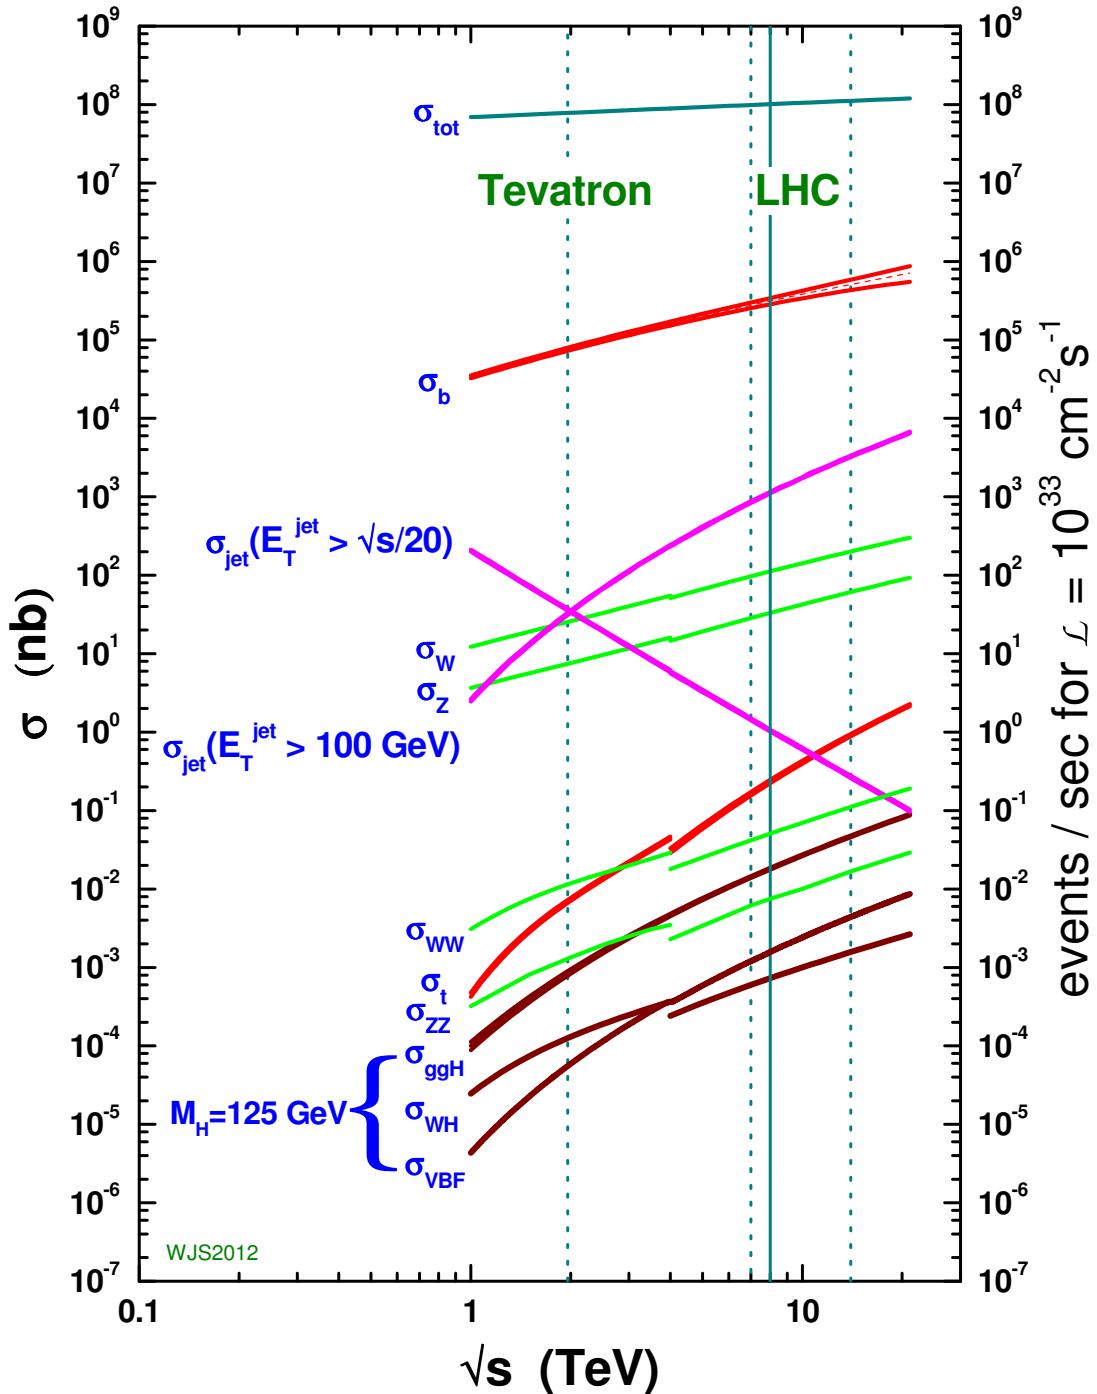

Figure 5.1: Scaling of cross sections with \sqrt{s} . Natasha: write more here

425 The first proton beams circulated in September, 2008. Nine days later an elec-
426 trical fault lead to mechanical damage and liquid helium leaks in the collider. This
427 incident delayed further operation until November 2009, when the LHC became
428 the world's highest energy particle collider, at 1.18TeV per beam. This first oper-
429 ational run continued until 2013, reaching 7 and 8 TeV collision energies. During
430 this run a particle with properties consistent with the Standard Model Higgs bo-
431 son was discovered. The next run began after a two year shutdown after upgrades
432 to the LHC and experiments. This run lasted from 2013 to 2018 reaching 13 TeV
433 collision energies. This analysis uses data from the second operational run.

434 5.1 LHC Layout and Design

435 The layout of the LHC is shown in Figure 5.2. The red and blue lines in the
436 figure represent the counter-circulating proton beams. The LHC is divided into
437 eight octants. Octant 4 contains the RF cavities that accelerate the protons and
438 octant 6 contains the beam dump system. Octants 3 and 7 house the collimation
439 systems for beam cleaning. The beams collide inside the four aforementioned
440 experiments. Each octant contains a curved and straight section. The LHC
441 magnets are built with NbTi superconductors cooled with super-fluid Helium to
442 2K, creating a 8.3T magnetic field to bend the proton beams.

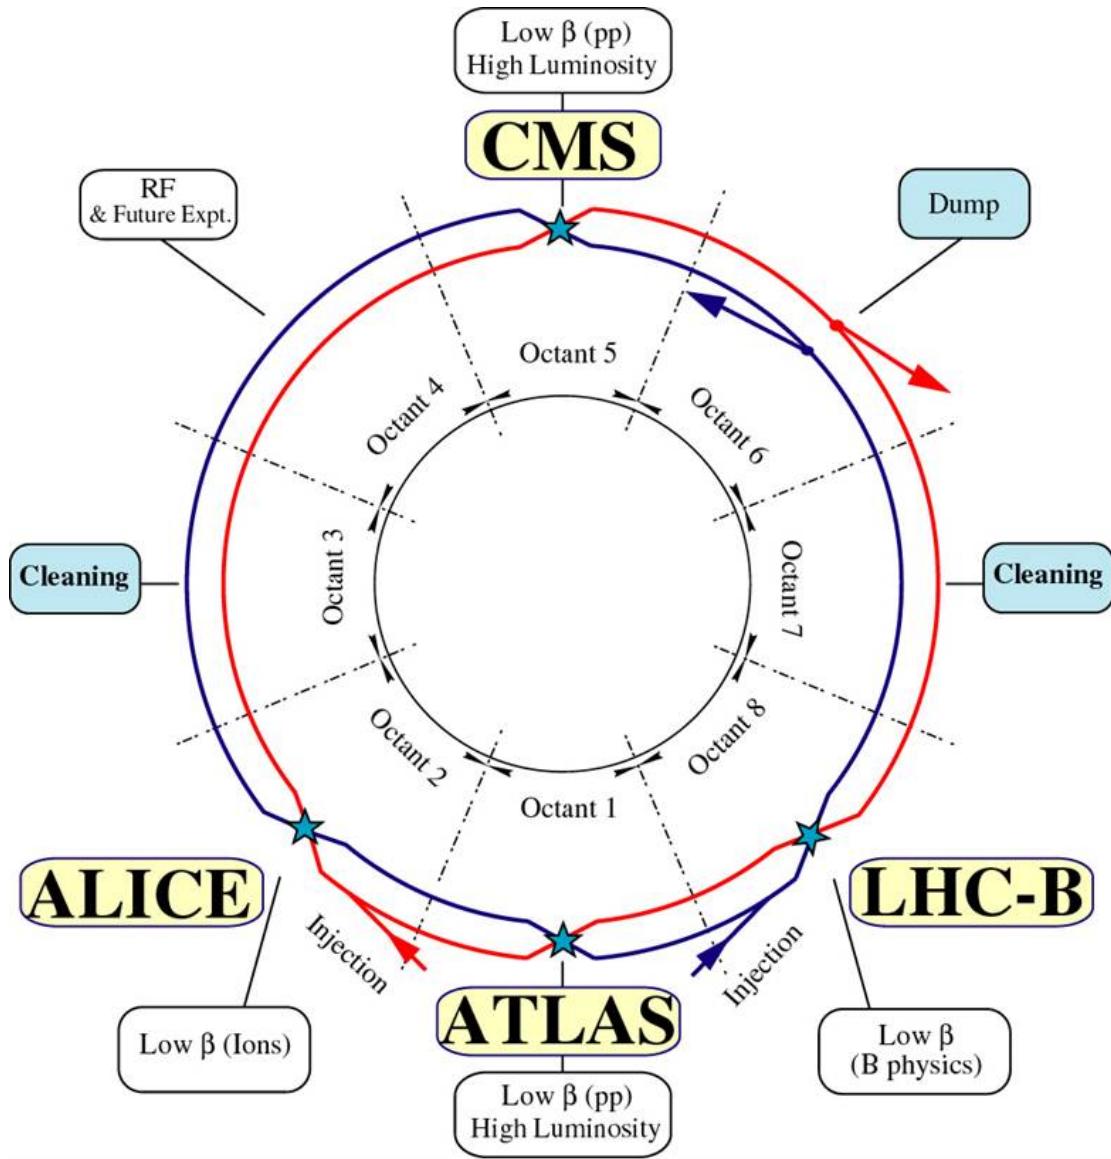

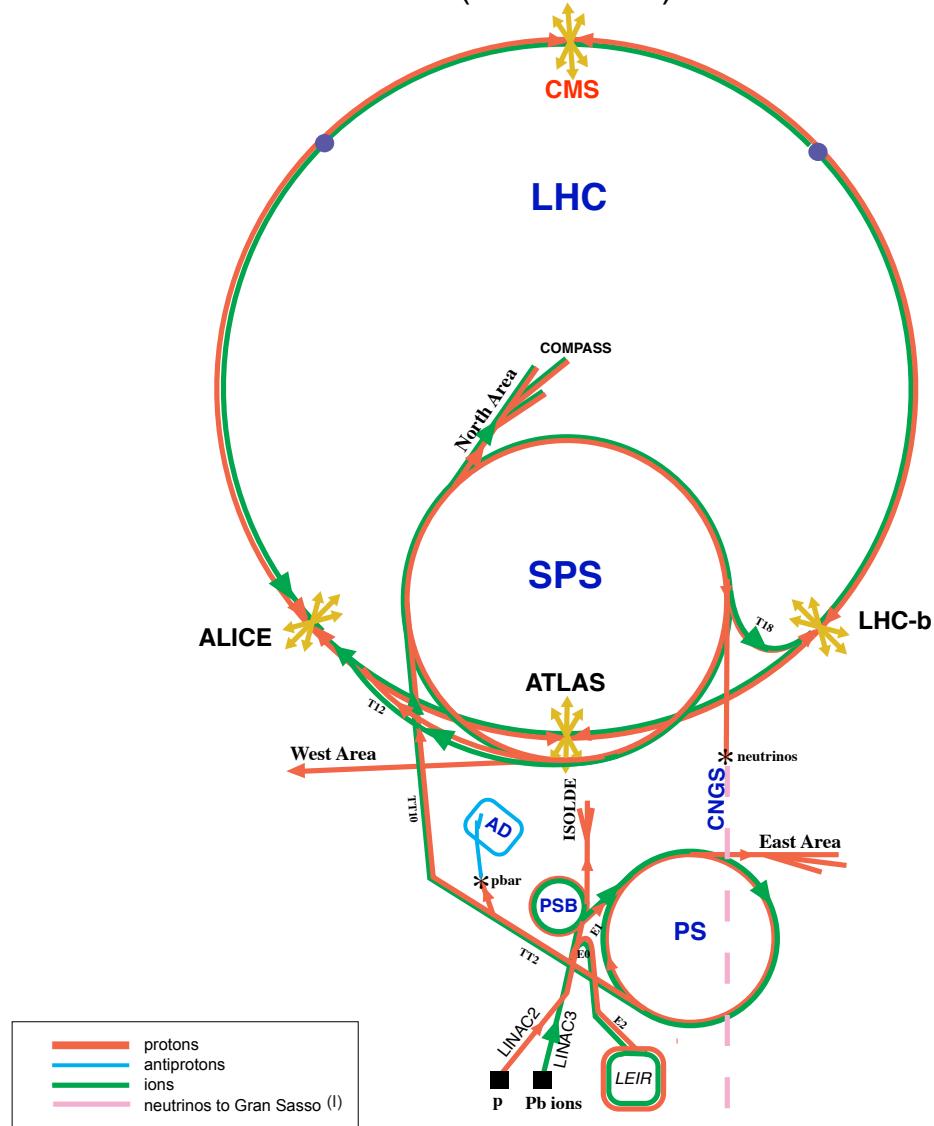

Figure 5.2: LHC Layout. Natasha write more

443 Four sequential particle accelerators are used to accelerate protons from rest
 444 as shown in Figure 5.3. First, Hydrogen gas is ionized to produce protons which
 445 are then accelerated to 50 MeV using Linac 2, a linear accelerator. The result-
 446 ing proton beam is then passed to three circular particle accelerators: Proton
 447 Synchrotron Booster, Proton Synchrotron, and Super Proton Synchrotron (SPS),

448 accelerating protons to 1.4, 25, and 450 GeV, respectively. Once the protons exit
449 the SPS, they are injected into the LHC at octant 2 and 8. Each proton bunch
450 contains $\sim 10^{11}$ protons. The spacing between bunches is 25 ns, which means
451 each beam contains 3564 bunches. However, some bunches are left empty due
452 to injection and safety requirements, yielding 2808 bunches per beam. Once the
453 proton beams are injected they are accelerated to 13 TeV.

Figure 5.3: LHC Accelerator. Natasha write more

454 As many new physics models predict cross-sections below the weak scale it was
455 important to design the LHC to be capable of collecting enough data, by running
456 in high luminosity conditions. The machine luminosity depends only on beam
457 parameters:

$$L = \frac{N_p^2 f}{4\epsilon\beta^*} F \quad (5.1)$$

458 where N_p is the number of protons per bunch, f is the bunch crossing frequency,
459 ϵ is the transverse beam emittance, β^* is the amplitude function at the collision
460 point, and F is the geometric luminosity reduction factor due to the beams crossing
461 at an angle (rather than head-on).

462 **Chapter 6**

463 **The ATLAS Detector**

464 The ATLAS detector measures the position, momentum and energy of parti-
465 cles produced in the proton collisions by using magnetic fields, silicon detectors,
466 sampling calorimeters, and gaseous wire detectors. It is located approximately
467 100 m underground at Point-1 around the LHC beam line and weighs 7000 metric
468 tons. The detector is 46 m long, 25 m high, 25 m wide as shown in Figure 6.2.
469 The detector can be divided into three subsystems: the Inner Detector (ID), the
470 Calorimeters, and the Muon Spectrometer (MS). Figure 6.3 shows an overview of
471 how different particles interact in the detector.

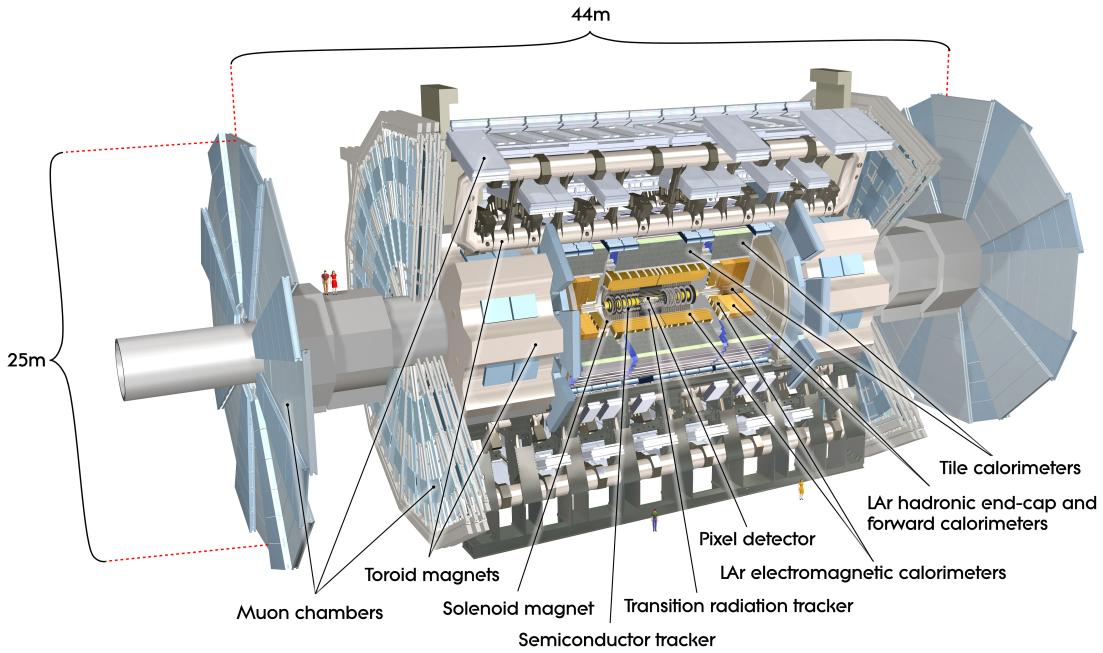

Figure 6.1: Big picture layout of ATLAS detector. Natasha: write more

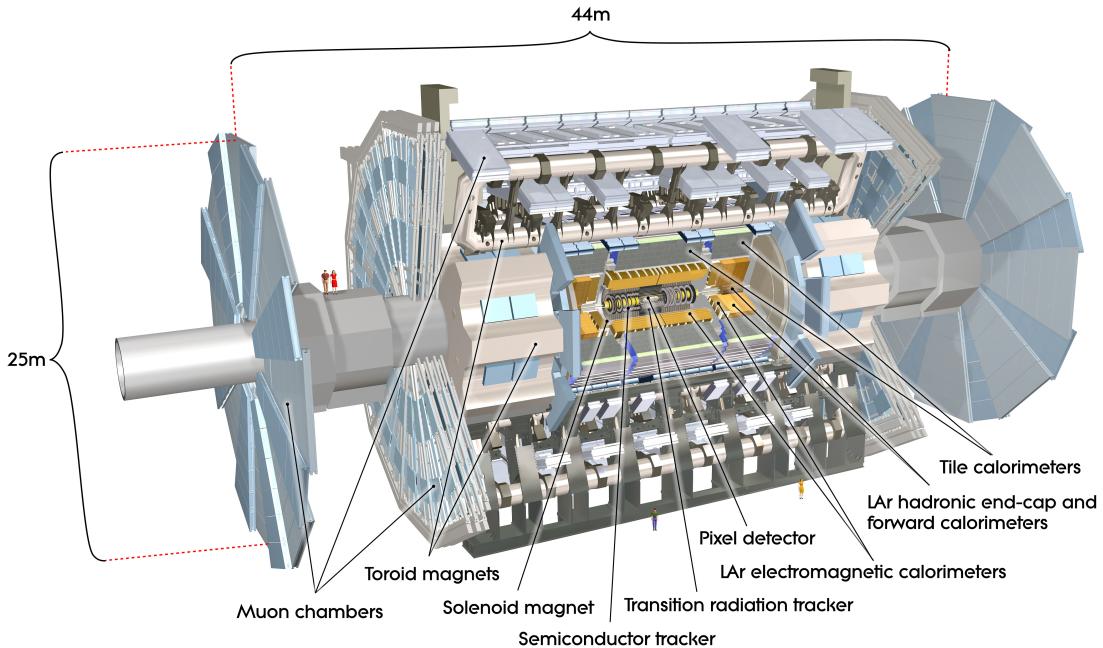

Figure 6.2: Big picture layout of ATLAS detector. Natasha: write more

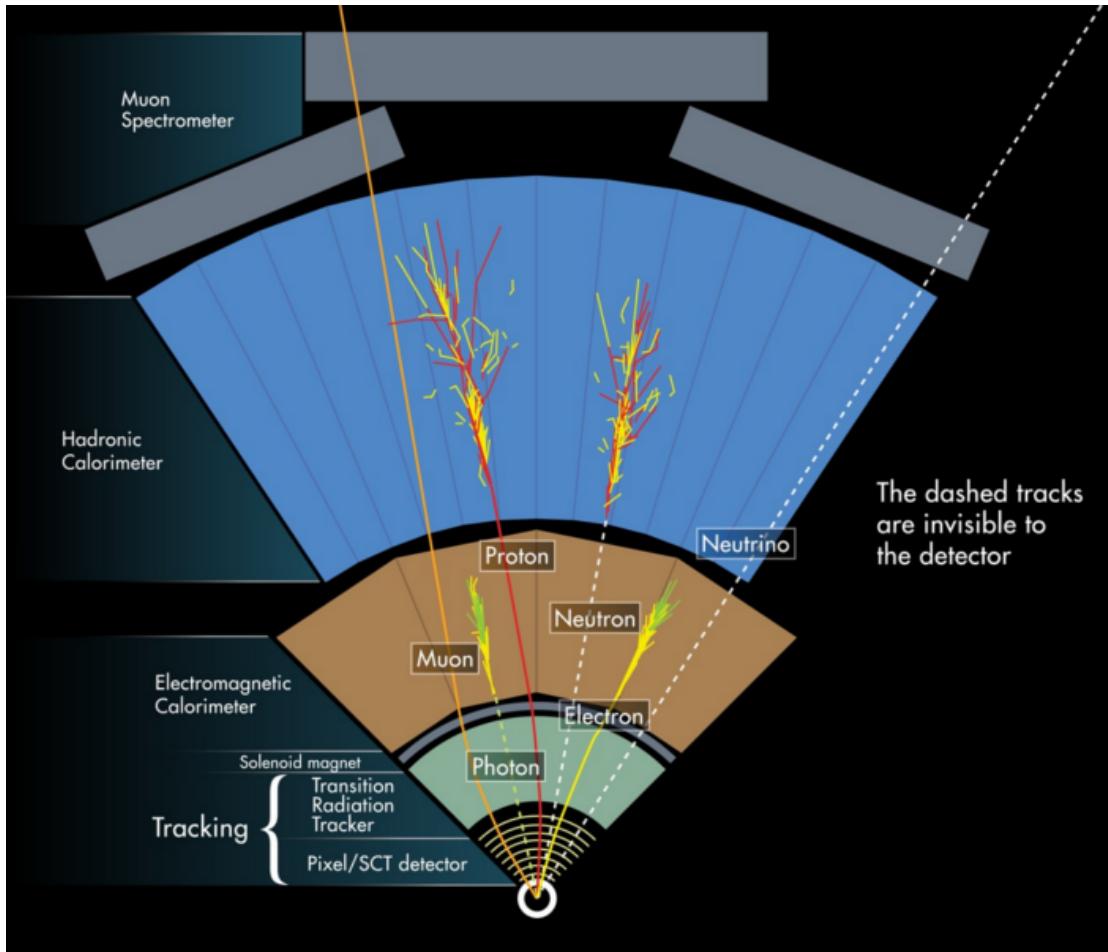

Figure 6.3: A simplified schematic of how different particles interact and are detected within ATLAS.

472 6.1 Coordinate System

473 The trajectory of particles within ATLAS is measured relative to the nominal
 474 interaction point. The z -axis points along the beam line, such that when the
 475 LHC is viewed from above, the counter-clockwise circulating beam points along
 476 the positive- z direction. The $x - y$ plane is transverse to the beam line, with the
 477 positive x -axis pointing towards the center of the LHC ring. The positive y -axis
 478 points vertically upward. The azimuthal angle, ϕ , is the angular distance about

479 the z -axis, with $\phi = 0$ along the x -axis. The polar angle from the z -axis is denoted
480 as θ . However, this quantity is not Lorentz invariant, like rapidity, $y = \frac{1}{2} \ln \frac{E+p_z}{E-p_z}$,
481 where E is the energy of the particle considered, and p_z , is it's momentum along
482 the z -axis. Pseudo-rapidity is preferred as $\Delta\eta$ is invariant under boosts along z
483 and particle production is approximately invariant under η . For massless particles,
484 rapidity and a related quantity, pseudorapidity, are the identical. The pseudora-
485 pidity is defined as: $\eta = -\ln \tan(\frac{\theta}{2})$. This quantity is preferred as it is purely a
486 geometric quantity, independent of particle energy. Angular separation between
487 particles in ATLAS are given by $\Delta R = \sqrt{\Delta\eta^2 + \Delta\phi^2}$. The distance from the
488 beamline is given by $r = \sqrt{x^2 + y^2}$

489 6.2 Inner Detector

490 The Inner Detector (ID) was designed to identify and reconstruct vertices,
491 distinguish pions from electrons, and measure the momentum of charged particles.
492 The ID uses three different technologies for particle reconstruction: the Pixel
493 Detector, Semiconductor Tracker (SCT), and the Transition Radiation Tracker
494 (TRT), shown in Figure 6.4 and 6.5. The entire ID is immersed in a 2T solenoidal
495 magnetic field parallel to the $+z$ -axis, causing charged particles to bend in the
496 transverse-plane, allowing particle momentum measurements.

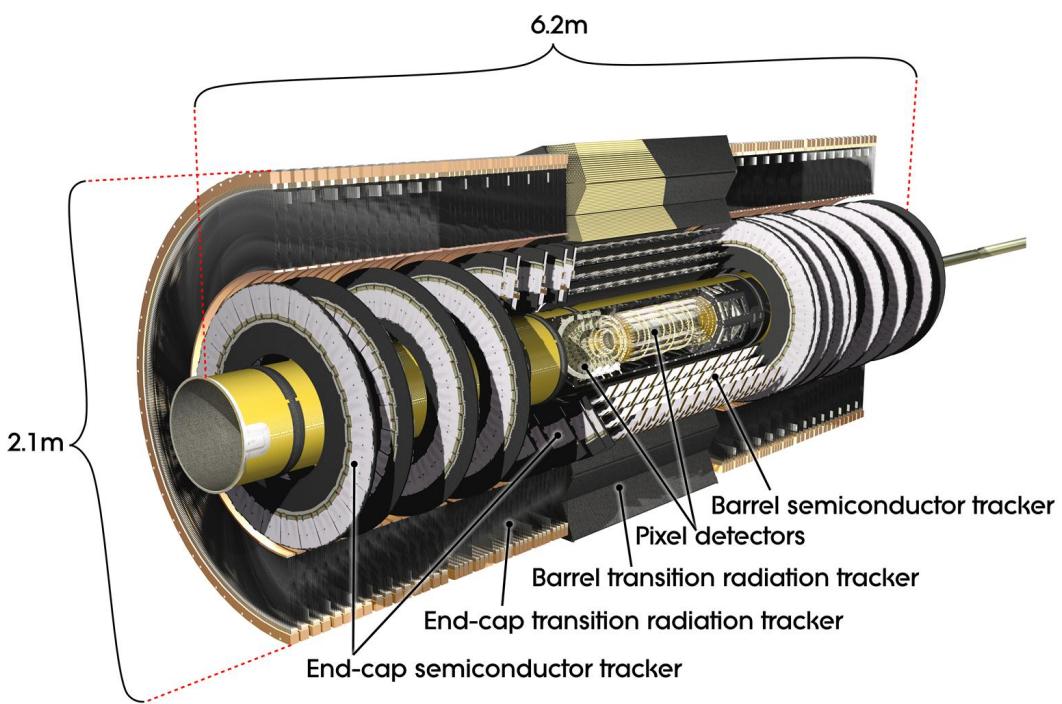

Figure 6.4: Layout of ATLAS Inner Detector

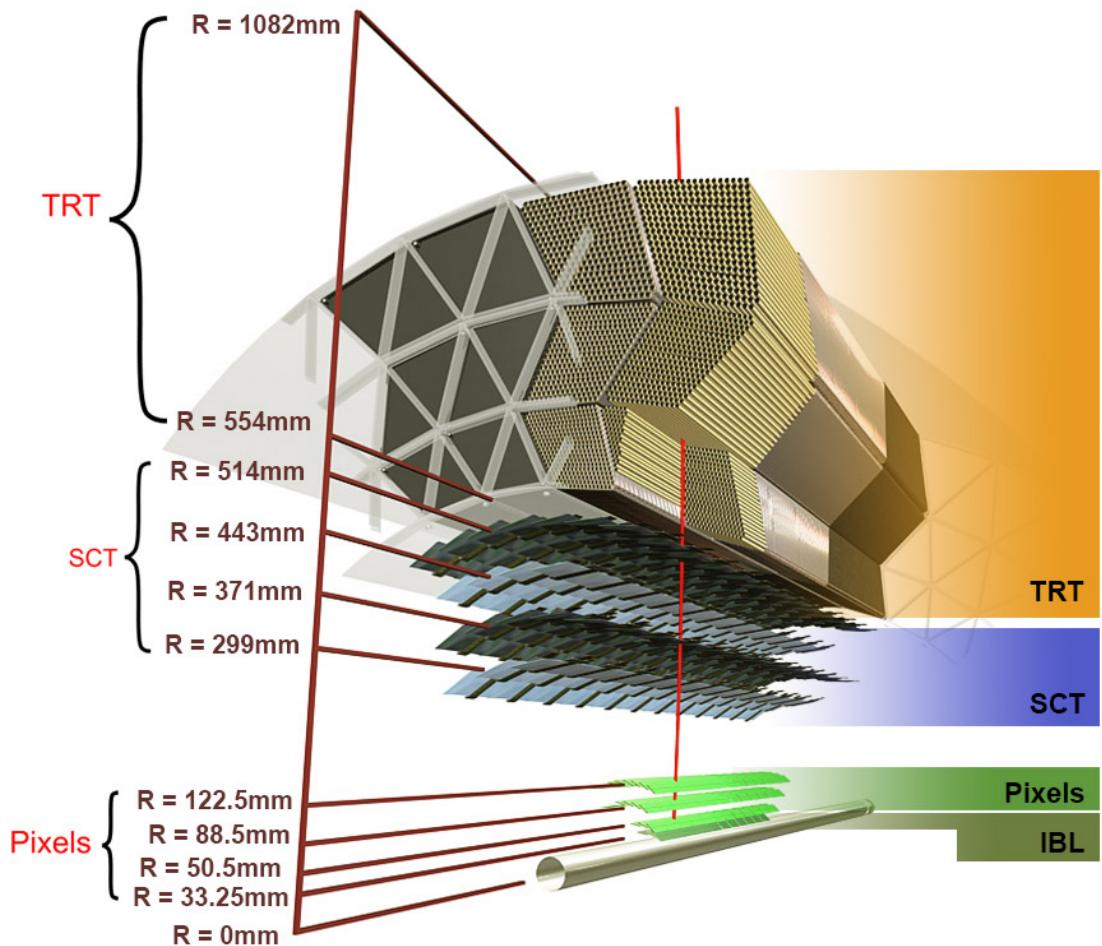

Figure 6.5: Layout of ATLAS ID Barrel System.

497 **6.2.1 Pixel Detector**

498 The pixel detector consists of four barrel layers between $r = 32.7$ and 122.5
499 mm, extending to $|z| = 400.5$ mm. The remaining detectors are arranged in bar-
500 rels and forward and backward rings. The innermost pixel barrel, the Insertable
501 b-Layer (IBL), only extends to $|z| = 332$ mm. The pixel detectors closer to the
502 beam line (larger η values) consists of six parallel cylindrical rings of pixel de-
503 tectors transverse to the beam line. The entire pixel detector consists of 1744
504 identical pixel sensors each with 46080 readout channels, totaling about 80 mil-
505 lion individual pixels. Most of the pixel sensors are $50 \times 400 \mu\text{m}^2$. Each pixel has
506 a position resolution of $14 \mu\text{m}$ in ϕ and $115 \mu\text{m}$ in the z direction.

507 **6.2.2 Semiconductor Tracker**

508 The SCT is located outside the pixel detector and has the same barrel and
509 endcap geometry as the pixel detector. SCT sensors are $80 \mu\text{m} \times 12$ cm with
510 a $80 \mu\text{m}$ strip pitch. In the barrel the strips are parallel to the z -axis and are
511 segmented in ϕ . In the endcaps, the strips extend radially. Sensors are grouped in
512 modules containing two layers of strips rotated 40 mrad with respect to each other.
513 This offset allows for the two-dimensional position of a track to be determined by
514 identifying the crossing point of the strips that registered a hit. SCT modules
515 measure tracks with an accuracy of $17 \mu\text{m}$ in $r - \phi$ and $580 \mu\text{m}$ in $z(r)$ in the
516 barrel (end-cap) region.

517 **6.2.3 Transition Radiation Tracker**

518 The transition radiation tracker (TRT), enveloping the SCT, is a gaseous
519 straw-tube tracker mainly used for electron/pion track separation. Each straw
520 is 4 mm in diameter and filled with a Xe- CO_2 - O_2 gas mixture. An anode wire at

521 the center of the straw is held at ground potential, while the walls of the straw
522 are kept at -1.4kV. When a charged particle passing through the TRT ionizes the
523 gaseous mixture, the resulting ions form an avalanche on the anode wire with a
524 gain of $\sim 10^4$. The signal from the anode wire is then digitized and discriminated.
525 Signals passing a low threshold cutoff are used to distinguish noise from tracks.
526 Signals passing a high threshold cutoff are sensitive to transition radiation (TR).
527 TR photons are emitted when charged particles pass between materials with dif-
528 ferent dielectric constants. The probability that a charged particle with energy E
529 and mass m passing between two materials emits a TR photon in the keV range
530 is proportional to $\gamma = E/m$. In the TRT straws these often then convert via the
531 photoelectric effect, causing a large avalanche triggering the high-threshold. Since
532 electrons have a smaller mass than pions, electron tracks are more likely to trig-
533 ger the high threshold. This then provides discrimination between electrons and
534 charged hadrons.

535 The barrel region of the TRT extends from $r = 563\text{-}1066$ mm and $|z| < 712$
536 mm. Barrel Straws are 144 cm long (divided $\sim \eta \approx 0$) and orientated parallel to
537 the beam direction. End-cap straws extend radially and are 37 cm long. There
538 are 53,544 straws in the barrel and 160,000 straws in the end-caps. Radiator mats
539 of polypropylene/polyethylene fibers in the barrel are aligned perpendicular to the
540 barrel straws (with holes for the straws to pass through). In the end-cap region,
541 radiator foils are layered between the radial TRT straws.

542 The arrival time of the signal pulse is sensitive to the distance between the
543 charged particle track and the anode wire and allows for a hit resolution of $130\mu\text{m}$.
544 The TRT extends to $|\eta| = 2.0$ and provides about 36 hits per track.

545 **6.3 Calorimeters**

546 The ATLAS electromagnetic and hadronic calorimeters (EMC and HCAL,
547 respectively) absorb and measure the energy of high energy hadrons, photons,
548 and electrons with $|\eta| < 4.9$. Both systems use sampling calorimeters which
549 consist of alternating layers of dense absorbing and active layers. In the absorbing
550 layer particles interact and lose energy, creating showers. These showers are then
551 detected and measured in the active layer. The amount of charge measured in the
552 active material scales with the energy of the incident particle, and thus provides a
553 measurement of the particle's energy. An overview of the layout of the calorimeter
554 system is shown in Figure 6.6.

555 The EMC measures and contains the energy of electromagnetically interacting
556 particles. It consists of layered accordion-shaped Lead absorber plates and elec-
557 trodes immersed in liquid Argon with 170k channels.. Using accordion-shaped
558 electrode and absorbers ensures ϕ symmetry and coverage. The EMC is com-
559 posed of a barrel part ($|\eta| < 1.475$), two end-caps ($1.375 < |\eta| < 3.2$), and a
560 presampler ($|\eta| < 1.8$). The presampler, containing only liquid Argon, corrects
561 for upstream energy losses of electrons and photons. The EMC barrel is segmented
562 into three layers. The first layer has finest segmentation with readout cells ex-
563 tending $\Delta\eta \times \Delta\phi = 0.025/8 \times 0.1$. This provides a precise shower measurements
564 used to separate prompt photons from $\pi^0 \rightarrow \gamma\gamma$ decays. The second layer has
565 coarser segmentation and is approximately 16 radiation lengths long. A radiation
566 length is the average distance an electron travels before losing all but $1/e$ of its
567 energy to bremsstrahlung. The last layer is the most coarse and measures the tail
568 of the electromagnetic shower. A schematic of the ECAL is shown in Figure 6.7.

569 The hadronic calorimeter located outside the EMC and is used to contain
570 and measure the energy of hadronically interacting particles. It consists of a tile

571 calorimeter (TileCal), hadronic end-cap calorimeter (HEC), and liquid Argon for-
 572 ward calorimeter (FCAL). TileCal is located behind the LAr EMC and uses steel
 573 absorbers and liquid Argon as the active material. TileCal consists of three barrel
 574 layers in the central and forward regions, extending up to $|\eta| < 1.7$. Photons
 575 generated from hadronic interactions are collected via wavelength-shifting fibers
 576 connected to photomultiplier tubes, as shown in Figure 6.8. The HEC lies behind
 577 the EMC endcap wheels. It uses copper absorbers and liquid Argon as the active
 578 material and covers $1.5 < |\eta| < 3.2$. Finally, the FCAL covers $3.1 < |\eta| < 4.9$
 579 and consists of three modules all using liquid Argon as the active material. The
 580 first module uses copper absorber and was designed for electromagnetic measure-
 581 ments. The second and third modules consist of tungsten absorber and are used
 582 to measure the kinematics of hadronically interacting particles. A schematic of
 583 the HCAL is shown in Figure 6.8.

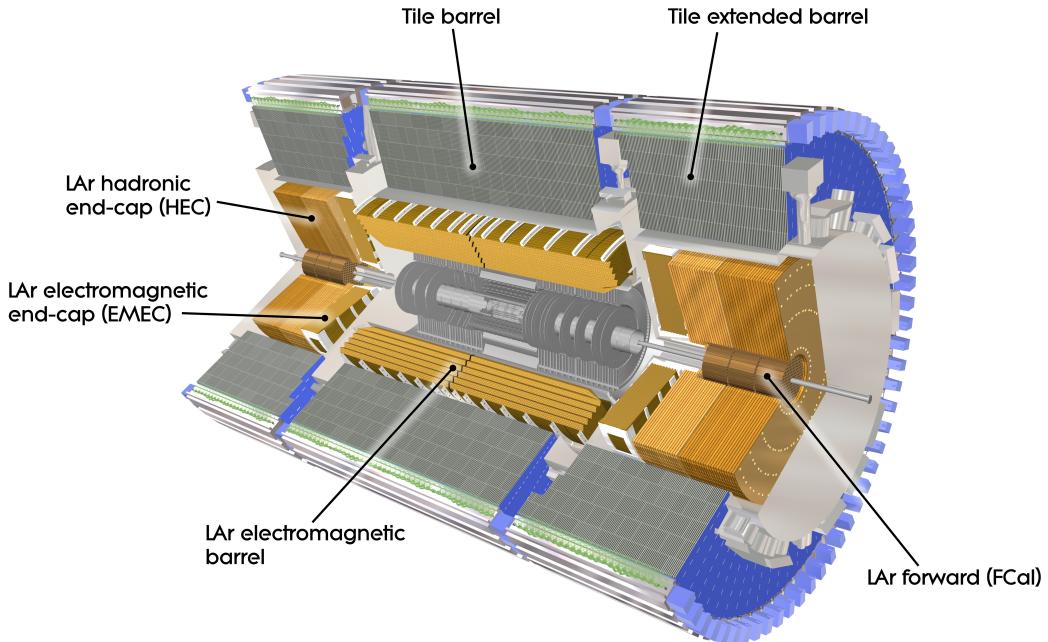

Figure 6.6: Overview of ATLAS electromagnetic and hadronic calorimeters.

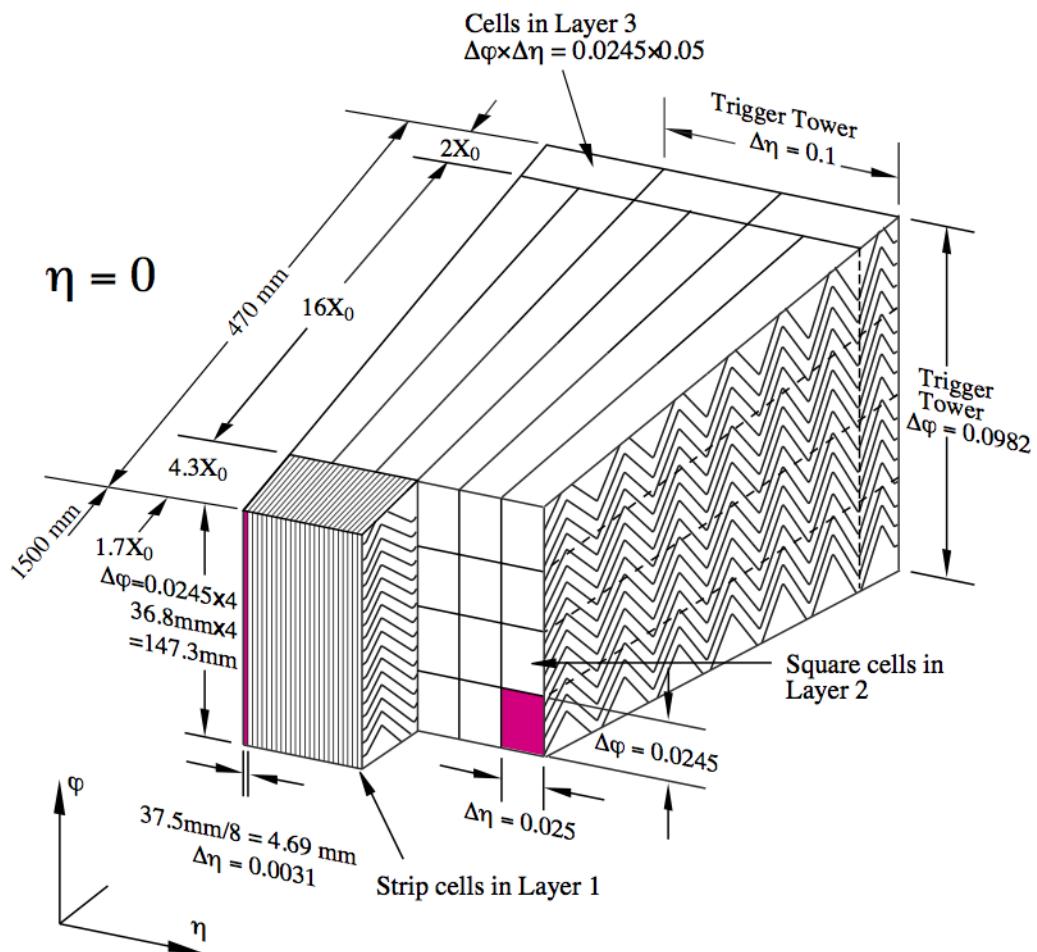

Figure 6.7: Schematic of ECAL.

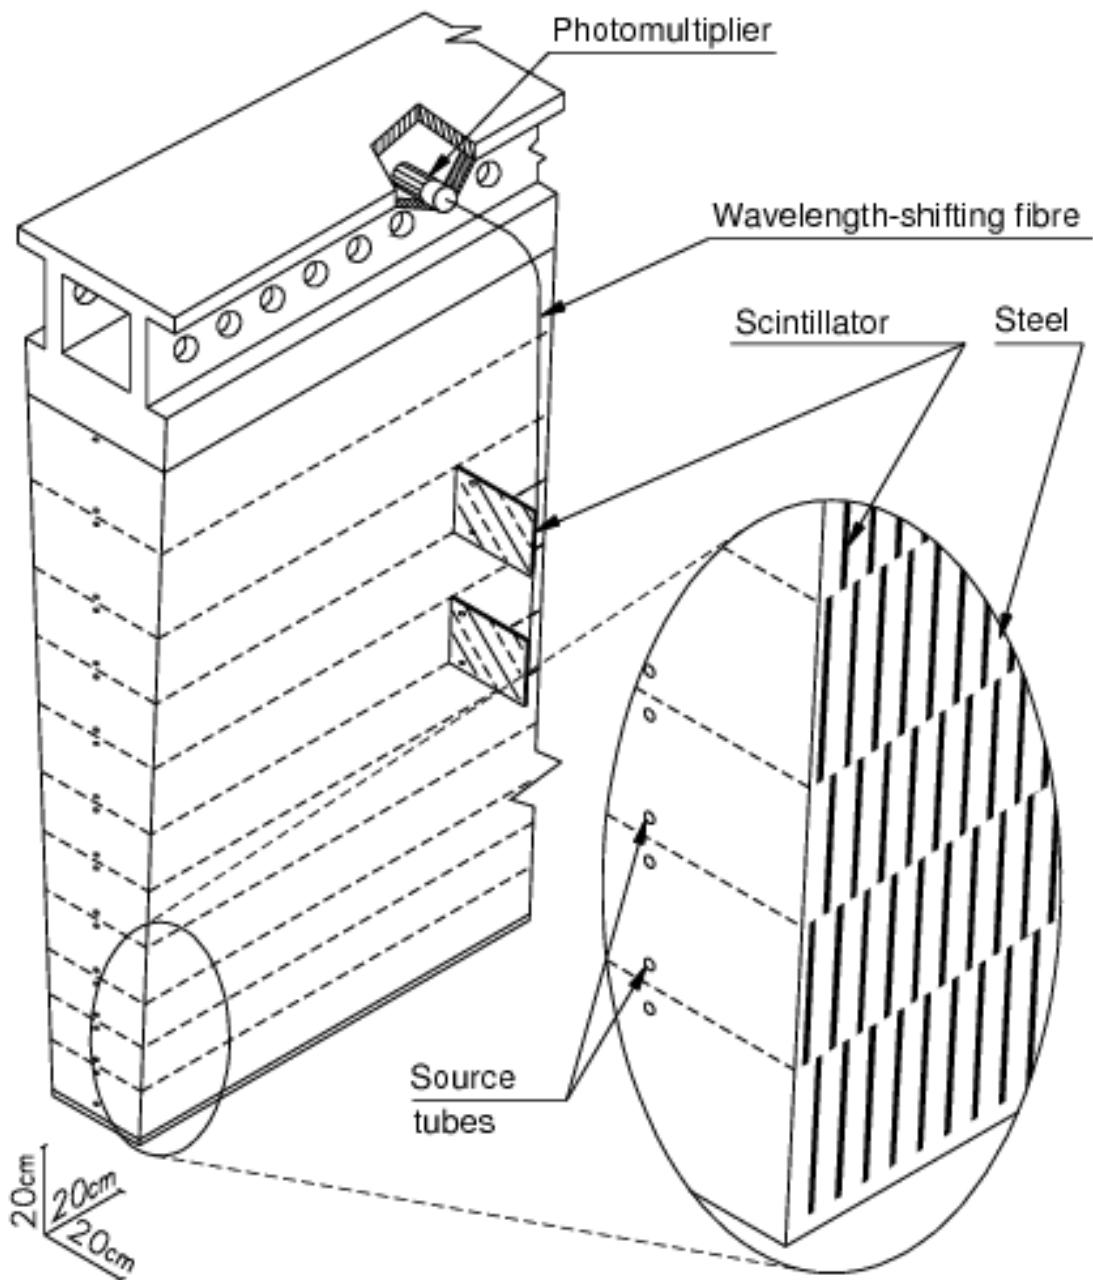

Figure 6.8: Schematic of HCAL.

584 The energy resolution of the calorimeter subsystems are:

$$585 \quad \frac{\sigma_E}{E} = \frac{10\%}{\sqrt{E}} \oplus 0.7\% \text{ EMC}$$

$$586 \quad \frac{\sigma_E}{E} = \frac{50\%}{\sqrt{E}} \oplus 3\% \text{ hadronic barrel}$$

$$587 \quad \frac{\sigma_E}{E} = \frac{100\%}{\sqrt{E}} \oplus 10\% \text{ hadronic end-cap}$$

588 6.4 Muon Spectrometer

589 The muon spectrometer (MS) is the outermost detector system in ATLAS.

590 Muons with a $p_T > 4$ GeV are energetic enough to reach the MS. To measure the
591 momentum of these muons barrel and end-cap toroid magnets are used covering
592 $|\eta| < 1.4$ and $1.6 < |\eta| < 2.7$. For $1.4 < |\eta| < 1.6$, a combination of the barrel
593 and end-cap toroidal magnetic fields bend muon trajectories. The detector in the
594 barrel region form three concentric rings at $R = 5, 7.5, 10$ m and are segmented
595 in ϕ to accommodate the magnets. The end-cap region consists of three circular
596 planes perpendicular to z and located at $|z| = 7.4, 14, 21.5$ m from the interaction
597 region. An additional detector at $|z| = 10.8$ m covers the transition region between
598 the barrel and end-cap.

599 The MS readout consists of four subsystems: Monitored Drift Tubes (MDT),
600 Cathode Strip Chambers (CSC), Resistive Plate Chambers (RPC), and Thin Gap
601 Chambers (TGC). The first two subsystems are used primarily for measuring
602 muon track parameters, while the RPC and TGC subsystems are used for muon
603 triggering. A schematic of this system is shown in Figure 6.9.

604 The MDT subsystem consists of precision tracking chambers for $|\eta| < 2.7$,
605 except for the inner most end-cap layer ($2.0 < |\eta| < 2.7$), where CSCs are used.
606 The basic unit of MDT chambers are thin walled Aluminum tubes with a diameter
607 of 3 cm and length of 0.9-6.2 m. These tubes are filled with a mixture of Ar-CO₂
608 gas with a 50μm W-Rn wire running down the center of the tube, which is kept at

609 3080 V. Since the maximum drift time of these chambers is ~ 700 ns, they are not
610 used for triggering. MDT chambers consist of 3-4 layers of tubes mounted on a
611 rectangular support system, as seen in Figure 6.10, orientated along ϕ to measure
612 the coordinate in the bending plane of the magnetic field with a resolution of 35
613 μm .

614 The MDT subsystem can only handle hit rates below $150\text{Hz}/\text{cm}^2$. For this
615 reason, CSCs are used in the innermost end-cap layer where hit rates are larger.
616 CSCs can handle hit rates up to $1000\text{Hz}/\text{cm}^2$. CSC are multiwire proportional
617 chambers. These chambers are filled with a Ar- CO_2 gas mixture and evenly spaced
618 wires kept at 1900 V. These wires are orientated in the radial direction but not
619 read out. Instead on one side of the cathode are copper strips parallel to the wires,
620 measuring η , while on the other side of the cathode are strips parallel to the wires
621 measuring ϕ . The width between strips is approximately 1.5 mm providing a
622 resolution of 60 μm in the bending-plane and 5 mm in the non-bending plane.

623 Since the CSC and MDT systems do not have prompt timing signals, the RPC
624 and TGC systems are used for triggering. The RPC system is used in the barrel
625 region ($|\eta| < 1.05$). RPC consist of two parallel resistive plates separated by a 2
626 mm insulated spacer with 100 mm spacing kept at 9.8 kV, as shown in Figure 6.11.
627 A gaseous mixture of $\text{C}_2\text{H}_2\text{F}_4$, C_4H_{10} , and SF_6 fills the space between the two
628 plates. Metallic strips on the outer faces of the plates are used to read out signals
629 produced by the gas ionizing. The middle barrel layer consists of two layers of
630 RPCs on either side of the MDT layer and one layer on the outermost MDT
631 layer. Each layer contains two orthogonal sets of metallic strips providing η and
632 ϕ measurements. The timing resolution of RPCs is 1.5 ns, and therefore may be
633 used to identify bunch crossings.

634 Finally, the TGCs are used in the end-cap regions and are primarily used to

635 provide L1 trigger decisions and ϕ measurements. TGCs are multi-wire propor-
 636 tional chambers consisting of arrays of gold-coated tungsten wires placed between
 637 two cathode planes. These wires are separated by 1.8 mm and cathodes are 1.4 mm
 638 from the wires. Orthogonal to the wires, on the opposite side of the cathode plane
 639 are copper strips held at 2900 V. The chambers are filled with a mixture of CO_2
 640 and n-pentane gas, the latter acts as a quenching gas to prevent avalanches initi-
 641 ated by secondary γ -rays from the primary avalanche. Figure 6.12 is a schematic
 642 of a TGC. The timing resolution of TGCs is less than 25 ns and therefore they
 643 are used for bunch crossing measurements.

6.5 Magnet System

A particles with charge, q , and velocity v , moving in magnetic field, B , experiences a force, $F = qv \times B$. This force can cause charged particles to have a curved trajectory in magnetic fields, which the ID and MS use to determine the particles p_T . The central solenoid provides the magnetic field for the ID and the toroidal magnets provide the magnetic field for the MS.

The layout of the magnet system is shown in Figure 6.13. The central solenoid consists of a single-layer Al-stabilized NbTi conductor coil wound inside an Al

652 support cylinder. The solenoid is 5.8 m long, 50 cm thick and has an inner radius
653 of 1.23 m. It is cooled to 4.5 K to reach superconducting temperatures and shares
654 the liquid argon calorimeter vacuum vessel to minimize material in the detector.
655 A current of 7.730kA produces a 1.998 T solenoidal magnetic field, pointing in
656 the $+z$ direction.

657 The toroidal magnet system consists of a barrel and two end-cap toroidal
658 magnets used to create a magnetic field outside the calorimeters that is orientated
659 along ϕ . Each barrel toroid is 25.3 m long with an inner and outer diameter of 9.4
660 and 20.1 m and weighs 830 tonnes. Endcap toroids are 5 m long with an inner and
661 outer radius of 1.65 and 10.7 m. Both toroid systems use Al-stabilized Nb/Ti/Cu
662 conductors. The magnetic field strength in the barrel and endcap regions are 0.5
663 and 1 T, respectively.

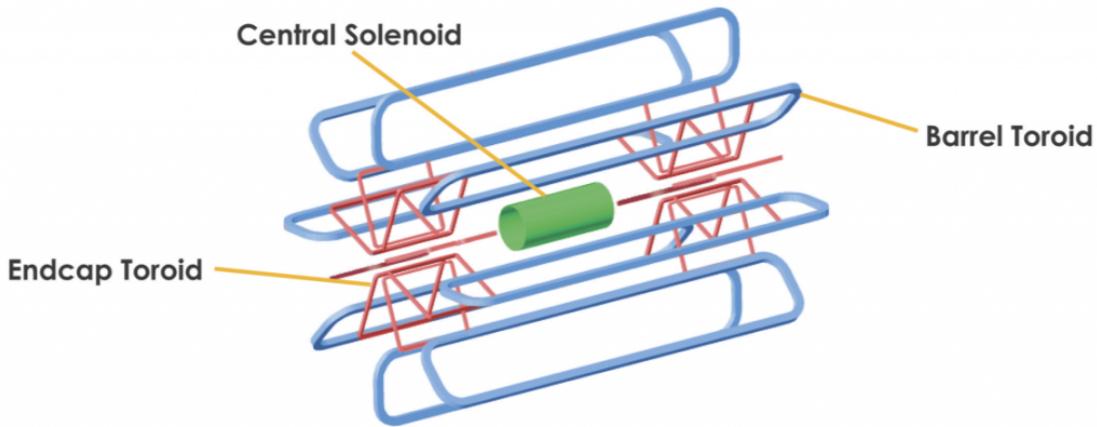

Figure 6.13: Layout of ATLAS magnet systems.

664 **6.6 Trigger System**

665 Since collisions occur every 25 ns and reading out all detector channels and
666 storing that information is not currently feasible (would require saving 60 million
667 megabytes per second), the majority of events are not kept for analysis. ATLAS

668 uses a multi-stage trigger system to select approximately 1,000 of the 1.7 billion
669 collisions that occur each second (corresponding to a rate of 1 kHz from the 40
670 MHz proton collision rate). The first stage of the trigger system is the hardware
671 level (L1) trigger. This trigger reduces the event rate to \sim 100 kHz by identifying
672 Regions-of-Interest (ROIs) containing high p_T leptons, photons, jets, or E_T^{miss} by
673 using information from RPCs, TGCs, and calorimeters to make a $2.5 \mu\text{s}$ decision.
674 This information is then passed to a high-level trigger (HLT) which further de-
675 creases event rates to \sim 1 kHz. The HLT uses finer granularity measurements
676 from the MS and ID to perform simplified offline reconstruction to decide which
677 events to keep.

Part IV

678

Method

679

680 **Chapter 7**

681 **Dataset and Simulated Samples**

682 **7.1 Dataset**

683 This analysis uses pp collision data collected from 2015 to 2018 at $\sqrt{s} = 13$
684 TeV, corresponding to 139/fb of data as shown in Figure 7.1 and 7.2. From this
685 dataset, only those events in which the tracker, calorimeters, and muon spectrom-
686 eter have good data quality are used. For a given event, the solenoid and toroidal
687 magnets must also be operating at their nominal field strengths. In addition to
688 this, events must pass further quality checks to reject events where detector sub-
689 systems may have failed. These selections reject events that containing LAr noise
690 bursts, saturation in the electromagnetic calorimeter, TileCal errors, and failures
691 in event recovery due to tracker failures. Events with information missing from
692 subsystems (usually due to busy detector conditions) are rejected. Events must
693 also contain a primary vertex with at least two associated tracks, where the pri-
694 mary vertex is selected as the vertex with the largest $\sum p_T^2$ over tracks associated
695 with the vertex and $p_T > 0.5$ GeV.

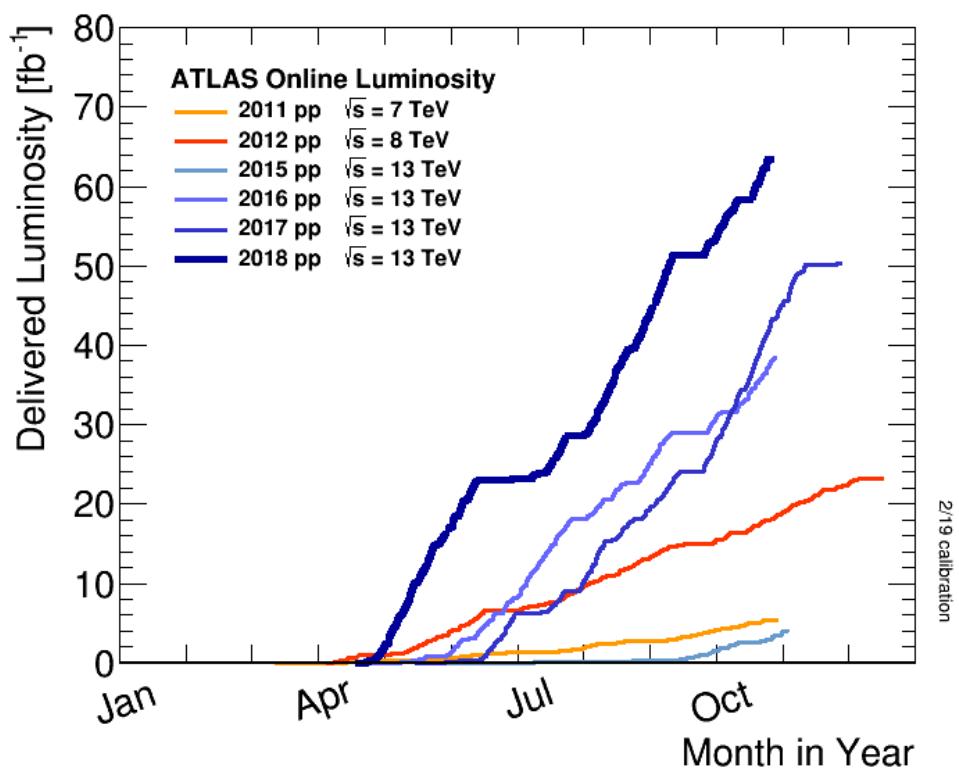

Figure 7.1: Integrated luminosity for data collected from ATLAS from 2011 - 2018

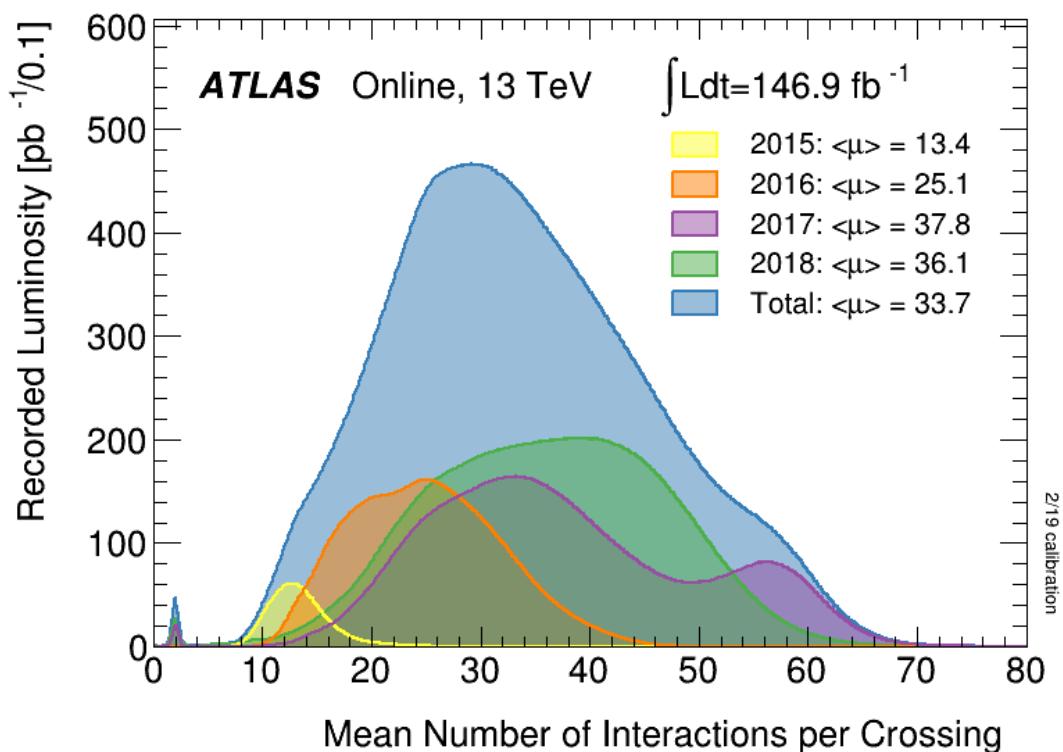

Figure 7.2: Mean number of interactions per crossing for data collected from ATLAS from 2011 - 2018

696 7.2 Simulated Samples

697 Samples are simulated in order to model backgrounds, evaluate signal ac-
698 ceptance, optimize event selection and estimate systematic and statistical uncer-
699 tainties. The dominant backgrounds for this analysis are $W/Z + \text{jets}$, diboson
700 (WZ/WW), $t\bar{t}$, single top and multijet production.

701 $W/Z+\text{jet}$ events are simulated using Sherpa 2.2.1 at NLO [cite [29]] and merged
702 with the Sherpa parton shower using the ME+PS@NLO prescription [13]. These
703 events are then normalized to NNLO cross sections. The $t\bar{t}$ and single-top back-
704 grounds are generated with Powheg-Box with NNPDF3.0NLO PDF sets in the
705 matrix element calculation [cite[35]]. For all processes, the parton shower, frag-
706 mentation, and underlying event are simulated using Pythia 8.320 with the A14
707 tune set[cite[ATL-PHYS-PUB-2014-02]]. Diboson processes are generated using
708 Sherpa 2.2.1.

709 Signal samples are simulated using MadGraph 5-2.2.2 [cite 42] and Pythia
710 8.186 with NNPDF230LO. RS Graviton samples are generated with $k/M_{PL}=1$.
711 HVT Model A (B) samples are simulated with $g_V = 1(3)$, as the difference in the
712 width of the samples is smaller than detector resolution. Model C is generated by
713 setting $g_H = 1$ and $g_f = 0$ to model VBF production of HVT bosons. Signals are
714 generated for masses between 300 GeV and 5 TeV.

715 **Chapter 8**

716 **Objects**

717 **8.1 Electrons**

718 Electrons are reconstructed from electromagnetic showers in the LAr EM
719 calorimeter. During reconstruction cells of $\Delta\eta \times \Delta\phi = 0.025 \times 0.025$ are grouped
720 into 3×5 clusters. These clusters are then scanned for local maxima that seed
721 electron clusters. These clusters must then be matched to ID track from the PV.
722 This requirement minimizes non-prompt electron and fake electron backgrounds.
723 Electrons must pass identification and isolation requirements. Electron identifica-
724 tion (loose, medium, tight) classification is based on a multivariate discriminant
725 that identifies electrons using a likelihood based method. For this analysis, events
726 are required to have one tight electron and no additional loose electrons. Elec-
727 trons are also required to be isolated. The electrons are considered isolated if the
728 quotient of the sum of the transverse momentum (of calorimeter energy deposits)
729 in a cone around the electron of size $\Delta R = 0.2$ and the transverse momentum
730 of the electron to be less than $0.015 * p_T$ or 3.5 GeV, whichever is smaller. This
731 requirement rejects non-prompt photons and other fake leptons. Electrons in this
732 analysis are also required to have $p_T > 30$ GeV and $|\eta| < 2.47$. Electrons are also

733 required to have $p_T > 30$ GeV.

734 Electrons are calibrated to determine data-driven scale factors using $J/\Psi \rightarrow$
735 ee , $Z \rightarrow ee$, $Z \rightarrow \ell\ell\gamma$ processes. These corrections account for the non-uniform
736 response of the detector which introduces modeling and reconstruction uncertain-
737 ties.

738 8.2 Muons

739 As muons traverse the entire detector, they are reconstructed from ID and
740 MS tracks. For this analysis the muon identification and isolation working points
741 are chosen to minimize the contributions from non-prompt muons. Towards this
742 end, each selected event must contain exactly one muon that passes the medium
743 identification working point, and no additional muons (that pass the loose working
744 point). For the medium working point, two types of reconstructed muons are
745 used: combined and extrapolated muons (CB and ME, respectively). For CB
746 muons, ID and MS tracks are reconstructed independently and a combined track
747 fit is performed by adding or removing MS tracks to improve the fit quality.
748 ME muons are reconstructed from only MS tracks with hits in at least two layers,
749 which ensures the track originates from the PV. ME muons extend the acceptance
750 for muon reconstruction outside the ID from $2.5 < |\eta| < 2.7$. The medium
751 identification working point uses CB and ME tracks. CB tracks must have at
752 least 3 hits in two MDT layers. ME tracks are required to have at least three
753 MDT/CSC hits. To further minimize contributions from fake muons, the selected
754 muons are required to be isolated from other tracks, as muons from W, Z decays are
755 often isolated from other particles. To insure the selected muons are isolated, the
756 scalar sum of the transverse momentum of tracks in a cone of $\Delta R = 0.3$ compared
757 to the transverse momentum of the muon must be less than 0.06. Muons are also

758 required to have $p_T > 30$ GeV.

759 Muons are calibrated using well-studied resonances $J/\Psi \rightarrow \mu\mu$ (low- p_T), $Z \rightarrow$
760 $\mu\mu$ (high- p_T). Figure 8.1 shows the combined muon p_T uncertainty from this
761 calibration. The total systematic uncertainty is less than 1% for all p_T ranges
762 considered in this analysis.

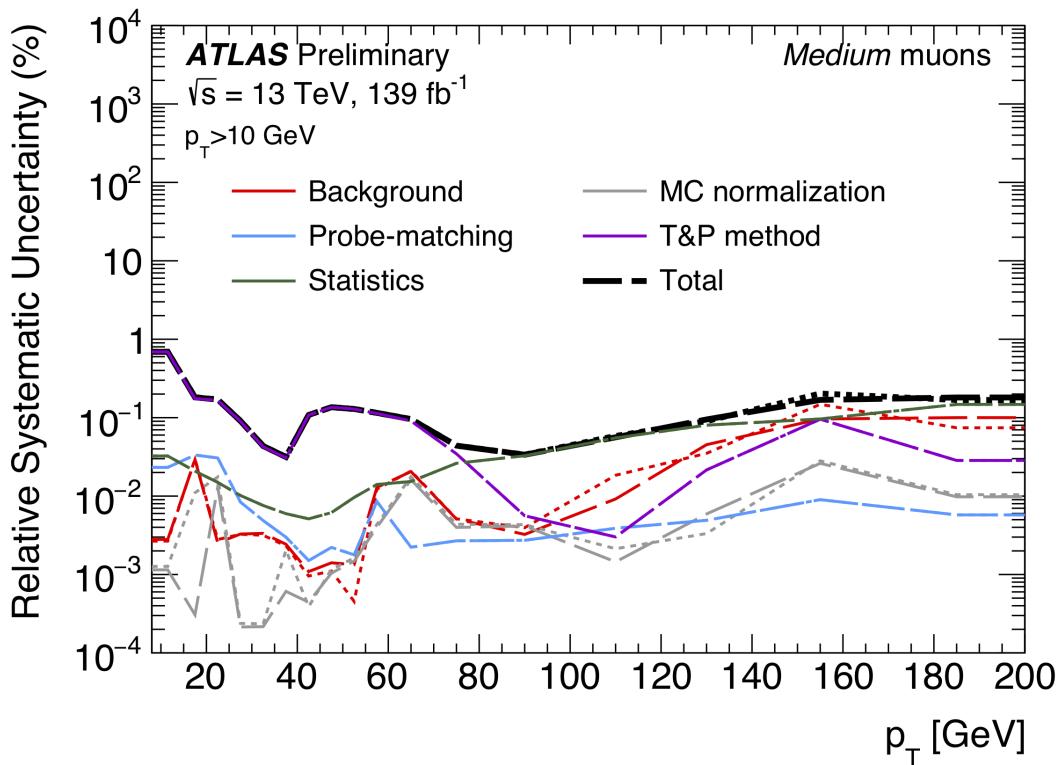

Figure 8.1: This figure shows the breakdown of the muon reconstruction efficiency scale factor measured in $Z \rightarrow \mu\mu$ as a function of p_T [5].

763 8.3 Jets

764 Three types of jets are used in this analysis: variable radius, small-R and
765 large-R jets. Variable radius jets are used to reconstruct Z bosons decaying to
766 two b -jets in the jet catchment area of large-R jet in the Merged regime. Small-R

767 jets are used to reconstruct the hadronically decaying W/Z candidates in the
768 resolved analysis and the forward jets from resonances produced through vector
769 boson fusion. Large-R jets are used to reconstruct the hadronically decaying boson
770 in the merged regime.

771 For all of these jet collections, the jet energy is calibrated sequentially as shown
772 in Figure 8.2. After the jet direction is corrected to point to the PV, the energy
773 of the jet is corrected. First, the jet energy is corrected to account for pileup
774 contributions based on the p_T and area of the jet (these corrections are extracted
775 from a $pp \rightarrow jj$ sample). Following this, another pileup correction is applied that
776 scales with μ and N_{PV} .

777 MC-based corrections are then applied that are meant to transform the jet
778 energy and η back to truth level. Therefore, these corrections account for the
779 non-compensating nature of the ATLAS calorimeters and inhomogeneity of the
780 detector. Following this, the Global Sequential Calibration is applied that re-
781 duces flavor dependence of jet calibrations and accounts for energy leakage of jets
782 outside the calorimeters. Finally, in-situ corrections are applied that account for
783 differences in jet responses between data and simulation ($\gamma/Z + \text{jet}$ and fake lep-
784 ton samples are used). These differences can be due to mismodelling of the hard
785 scatter event, pile-up, jet formation, etc.

786 To further reject fake jets, jets must pass quality requirements based on the
787 following variables ([cite P42]):

- 788 - f_Q^{LAr} : fraction of energy of jet's LAr cells with poor signal shape
- 789 - f_Q^{HEC} : fraction of energy of jet's HEC cells with poor signal shape
- 790 - E_{neg} : sum of cells with negative energy
- 791 - f_{EM} : fraction of jet's energy deposited in EM calorimeter

- 792 - f_{HEC} : fraction of jet's energy deposited in HEC calorimeter
- 793 - f_{max} : maximum energy fraction in any single calorimeter layer
- 794 - f_{ch} : ratio of the scalar sum of the p_T of a jet's charged tracks to the jet's p_T
- 795 Jets selected for the resolved analysis must pass one of the following criteria:
- 796 - $f_{HEC} > 0.5$ and $|f_Q^{HEC}| > 0.5$ and $\langle Q \rangle > 0.8$
- 797 - $|E_{neg}| > 60$ GeV
- 798 - $f_{EM} > 0.95$ and $f_Q^{LAr} > 0.8$ and $\langle Q \rangle > 0.8$ and $|\eta| < 2.8$
- 799 - $f_{max} > 0.99$ and $|\eta| < 2$
- 800 - $f_{EM} < 0.05$ and $f_{ch} < 0.05$ and $|\eta| < 2$
- 801 - $f_{EM} < 0.05$ and $|\eta| > 2$

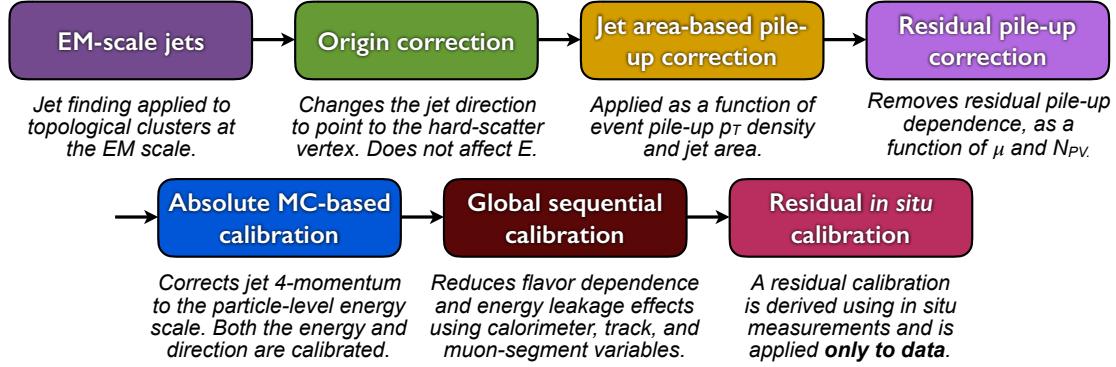

Figure 8.2: [8] This diagram shows the calibration stages for EM jets.

802 **8.3.1 Small-R jets**

803 Small-R jets are used to reconstruct the hadronically decaying W/Z candi-
804 date when the two resulting jets are well-separated in $\eta\text{-}\phi$ space. Small-R jets
805 are also used to identify forward jets from resonances produced through vector
806 boson fusion. Small-R jets are constructed from topologically connected clusters
807 of calorimeter cells (topoclusters), seeded from calorimeter cells with energy de-
808 posits significantly above the noise threshold. These cells are then used as inputs
809 to the $anti-k_t$ algorithm [16] with a radius parameter, $R = 0.4$.

810 Jets used in this analysis must have $p_T > 30$ GeV and $|\eta| < 2.5$. To further
811 reduce fake jets the jet-vertex-tagger (JVT) is used to reject pile-up jets [7]. The
812 JVT uses two track-based variables, corrJVF and R_{p_T} to calculate the likelihood
813 that the jet originated from the PV. The corrJVF compares the scalar sum of the
814 p_T of tracks associated with the jet and PV to the scalar sum of the p_T of tracks
815 associated with the jet. This variable also includes a correction that reduces the
816 dependency of corrJVF with the number of reconstructed vertices in the event.
817 The other discriminant, R_{p_T} , is given by the ratio of the scalar sum of the p_T of
818 tracks associated with the jet and PV to the p_T of the jet. Both of these variables
819 peak around zero for pileup jets, as these jets are unlikely to have tracks associated
820 with the PV. JVT cuts are applied to all jets with $p_T > 120$ GeV. Central jets
821 ($|\eta| < 2.4$) are required to have a $JVT > 0.59$ and forward jets ($2.4 < |\eta| < 2.5$)
822 are required to have $JVT > 0.11$.

823 **8.3.2 Large-R jets**

824 Large-R ($R = 1.0$) jets are used to reconstruct the hadronically decaying W/Z
825 candidate when the resulting jets are not well-separated in $\eta\text{-}\phi$ space, and overlap
826 forming one large-R jet. Track-Calorimeter Clusters (TCCs) are used to reconstruct these

jets [cite ANA 50]. These jets are constructed using a pseudo particle flow method
 using ID tracks matched to calorimeter clusters. To remove contamination in the
 jet from pileup and the underlying event, jets are trimmed using a re-clustering
 algorithm. This algorithm removes subjets with $p_T^{subjett} < 0.1 p_T^{jet}$.

The angular resolution of the calorimeter degrades sharply with jet p_T , but the
 jet energy resolution improves. The tracker has excellent angular resolution which
 improves with p_T . Therefore, by matching tracks to jets, TCCs have more precise
 energy and angular resolution than jets constructed from calorimeter information
 only. These jets are required to have $p_T > 200$ GeV, $|\eta| < 2.0$ and $m_J > 50$ GeV.

TCC jets are trimmed as detailed in [cite ANA 45], which suppresses pileup
 and soft radiation in the jet, the jet mass is calculated as the four-vector sum
 of the jet's constituents (assuming massless constituents). The jet mass peaks
 around the W/Z boson mass for $W/Z \rightarrow qq$ jets, and more broadly for quark and
 gluon induced jets.

These jets are then tagged as W jet if it passes optimized jet mass and sub-
 structure (D_2) cuts for W bosons, and a Z jet if it passes the cuts for the Z
 boson. The jet substructure variable D_2 is given by the ratio of energy correlation
 functions. These functions are derived from the energies and pair-wise angles of
 a jet's constituents [cite ANA 46, 47]:

$$D_2^{\beta=1} = E_{CF3} \left(\frac{E_{CF1}}{E_{CF2}} \right)^3 \quad (8.1)$$

where the energy correlation functions are defined as:

$$E_{CF1} = \sum_i p_{T,i} \quad (8.2)$$

$$E_{CF2} = \sum_{ij} p_{T,i} p_{T,j} \Delta R_{ij} \quad (8.3)$$

$$E_{CF3} = \sum_{ijk} p_{T,i} p_{T,j} p_{T,k} \Delta R_{ij} \Delta R_{jk} \Delta R_{ki} \quad (8.4)$$

848 A two-dimensional optimization of the jet mass and D_2 thresholds was per-
 849 formed to provide maximum sensitivity for this analysis. This optimization was
 850 done by maximizing the signal sensitivity (using HVT W' and G_{KK} samples)
 851 against the single quark and gluon jet backgrounds in jet p_T bins. Figure 8.3
 852 shows the optimized thresholds on D_2 and jet mass as a function of jet p_T . Figure
 853 8.4 shows the efficiency of the optimized W/Z taggers as a function of jet p_T .

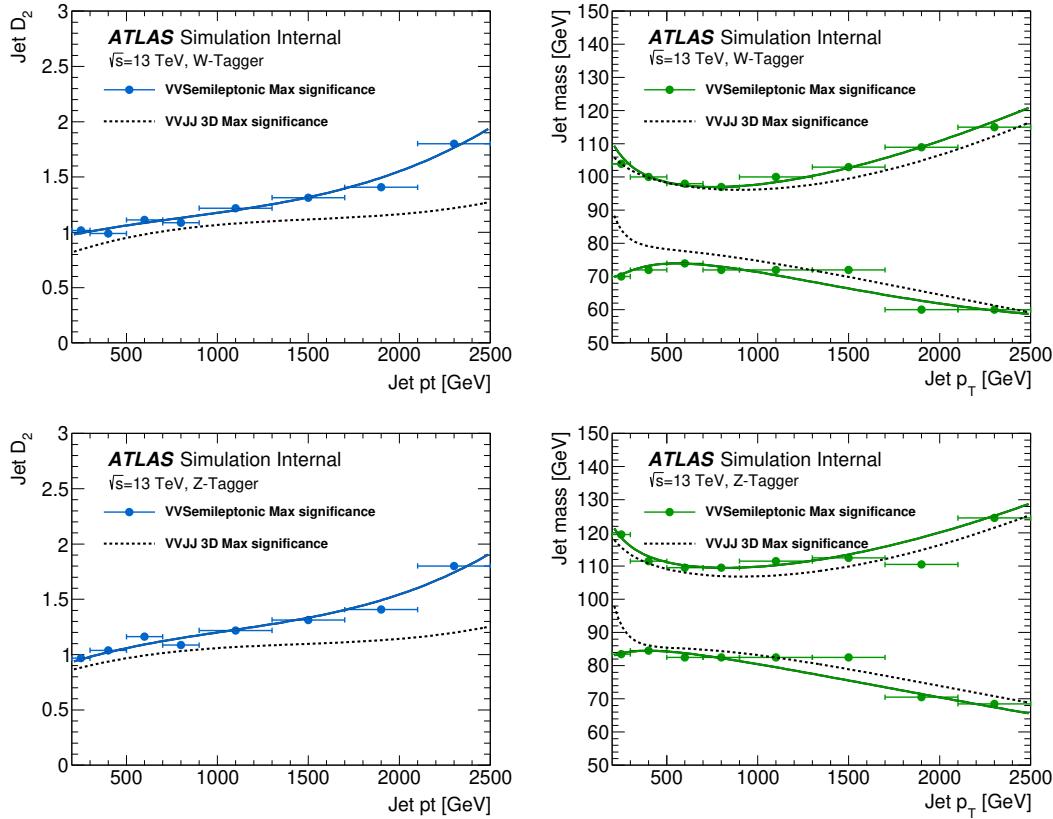

Figure 8.3: The upper cut on D_2 (a) and jet mass window cut i.e. the upper and lower boundary of the mass (b) of the W -tagger as a function of jet p_T . Corresponding values for Z -tagger are shown in (c) and (d). The optimal cut values for maximum significance are shown as solid markers and the fitted function as solid lines. Working points from $VV \rightarrow JJ$ [ATLAS-HDBS-2018-31-002] is also shown as dashed lines as a reference. Natasha reword?

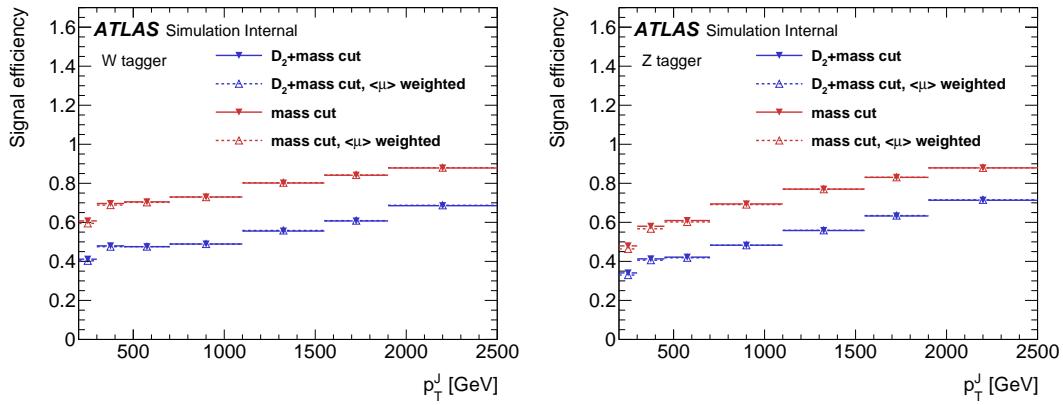

Figure 8.4: Natasha write caption

854 8.3.3 Variable Radius jets

855 To more accept more boosted Z bosons decaying to $b\bar{b}$ that would normally be
 856 rejected due to topological cuts discussed 9.4 variable radius (VR) track jets are
 857 used to identify b -jets (discussed in 8.3.4) within the catchment area of large- R
 858 jets [15]. VR jets are constructed from ID tracks using the anti- k_t algorithm with
 859 a radius parameter that depends on the p_T of the track, shown in Equation 8.5.

$$R_{eff}(p_{T,i}) = \frac{\rho}{p_{T,i}} \quad (8.5)$$

860 For this search $\rho = 30$ GeV and an lower and upper limit on cone size are set
 861 to 0.02 and 0.4, respectively, to prevent unphysical asymptotic behavior of ρ .
 862 Collinear VR jets are possible, so track jets that are not separated by the the
 863 smaller jet's cone size are not used. Additionally, VR jets are required to have
 864 $p_T > 10$ GeV and $|\eta| < 2.5$.

865 **8.3.4 Jet Flavor Tagging**

866 To further classify events, the small-R and VR jets originating from a b-quark
867 are classified using a multivariate b -tagging algorithm (BDT), MV2c10 [cite G 210
868 199]. This algorithm uses the impact parameters of the jet's ID tracks, secondary
869 vertices (if they exist), and reconstructed flight paths of b and c hadrons in the
870 jet to determine if the jet was induced by a b -quark. For this analysis the 85%
871 efficient working point of this algorithm is used giving c , τ , and light-flavor jet
872 rejection of 3, 8, and 34 respectively in simulated $t\bar{t}$ samples.

873 **8.4 MET/Neutrinos**

874 As neutrinos are uncharged and colorless they do not leave tracks or jets in
875 the detector. For this reason, neutrinos are reconstructed as the missing energy
876 in the event, E_T^{miss} . Mathematically, E_T^{miss} is the negative vector sum of p_T all
877 the physics objects and an extra "soft" term. The "soft" term accounts for energy
878 deposits not associated with any of the objects in the event. For this analysis
879 the soft term is given by the sum p_T of all ID tracks not associated with objects
880 in the event. The selected tracks must be matched to the primary vertex, which
881 decreases pile-up contamination [cite G 217 218].

882 **8.5 Overlap Removal**

883 Reconstructed jets and leptons in this analysis can arise from the same energy
884 deposits. For instance, a cluster of energy from an electron can also be a valid
885 calorimeter seed for a jet. To mitigate this confusion of multiple objects originating
886 from a single jet or lepton overlapping objects are removed via a procedure referred
887 to as overlap removal. In this procedure the separation of the two objects, $\Delta(R)$,

888 determines which object is removed from the event.

889 The overlap selections used in this analysis are:

- 890 - when an electron shares a track with another electron with the lower p_T
891 electron is rejected, as it is more likely to be a fake electron
- 892 - when a muon and electron share a track the muon is rejected if it is a
893 calo-muon, otherwise the electron is rejected
- 894 - when $\Delta R < 0.2$ for an electron and jet, the jet is rejected to maximize signal
895 acceptance
- 896 - when $\Delta R > 0.2$ for an electron and jet, the electron is rejected as likely
897 originated from decays within the jet
- 898 - when $\Delta R < \min(0.4, 0.04 + 10\text{GeV}/p_T^\mu)$ the muon is rejected, again maximiz-
899 ing signal acceptance, otherwise the jet is rejected
- 900 - when $\Delta R < 1.0$ for the a large-R jet and electron, the jet is rejected

901 8.6 Reconstructed Resonance Mass (m_{WV})

902 The WV system mass, m_{WV} is reconstructed from the lepton, neutrino, and
903 hadronically-decaying boson candidate. The momentum of the neutrino along the
904 z -direction is obtained by constraining the W boson mass of the lepton neutrino
905 system to be $80.3 \text{ GeV}/c^2$. For complex solutions to this constraint, p_Z is taken
906 as the real component of the solution. For real solutions, the one with the smaller
907 absolute value is used. For the resolved analysis, m_{WV} is reconstructed by con-
908 straining the $W(Z)$ dijet system in the SRs, which improves the mass resolution:

$$p_{T,jj}^{corr} = p_{T,jj} \times \frac{m_{W/Z}}{m_{jj}} \quad (8.6)$$

$$m_{jj}^{corr} = m_{W/Z} \quad (8.7)$$

909 where m_{jj} and $m_{W/Z}$ are the reconstructed invariant mass of the hadronically-
910 decaying W/Z boson and the PDG values of the W/Z boson masses, respectively.
911 The reconstructed resonance mass is the final discriminating variable in this anal-
912 ysis. The distribution of this variable in the CR and SRs are used in the final
913 likelihood fit to search for evidence of an excess of events due to BSM resonances.
914 The distribution of m_{WV} are shown in Figures 13.1-13.9.

915 **Chapter 9**

916 **Event Selection and**

917 **Categorization**

918 To search for these new resonances, the simulated background and signal sam-
919 ples are analyzed to determine a series of optimized cuts are used create signal
920 regions (SR) to identify the leptonic and hadronic decay products of the reso-
921 nance. In these regions, the resonance mass is calculated as the combined system
922 mass of the leptonic and hadronic systems as described in 8.6. The expected res-
923 onance mass distribution from the backgrounds and signal samples are compared
924 to data to search for the existence of these BSM signals (also known as a "bump
925 hunt"). Control regions enriched in the dominant backgrounds, $t\bar{t}$ and $W+\text{jets}$
926 (TCR and WCR, respectively) are constructed to be orthogonal to SRs and used
927 to determine the normalization of the $t\bar{t}$ and $W+\text{jets}$ backgrounds in SRs.

928 Events are classified as produced via non-VBF or VBF modes using a Re-
929 curisve Neural Network described in 9.3. VBF W' and Z' and ggF W' and Z'
930 resonances studied have unique SR and CR selections to maximize analysis sen-
931 sitivity. RS Graviton signals are probed using the same selections as the ggF Z'
932 signal. Additionally, more massive resonances are more likely to have boosted

933 W/Z bosons. As the boost of the hadronically decaying boson increases the sepa-
934 ration of its hadronic decay products decreases. When the hadronically decaying
935 boson has sufficient boost, the two quarks will overlap and not be identified sep-
936 arately. For this reason, a set of "resolved" selections are used when the hadronic
937 decay products are reconstructed separately, and "merged" selections when the
938 decay products overlap and identified as a single object in the event. A W/Z
939 tagger identifies merged jets as originating from a W/Z bosons based on jet sub-
940 structure and mass cuts. However, the more boosted the jet is the less likely it is
941 to pass the jet substructure cut, due to track merging. Consequently, the merged
942 selection uses a high purity region (HP), which requires that the jet pass both
943 cuts, and low purity (LP) region where the jet can fail the jet substructure cut.
944 These selections are summarized in 9.4.

945 The aforementioned SR definitions veto events with b -jets to minimize $t\bar{t}$ con-
946 tamination. However, b -jets are anticipated from W' resonances from the hadron-
947 ically decaying Z boson. To increase the signal acceptance of these resonances,
948 a $Z \rightarrow bb$ tagger is used to construct additional SR and CRs called the "tagged"
949 regions (and "untagged" if the event fails the $Z \rightarrow bb$ tagger).

950 9.1 Pre-selection

951 Before applying topological cuts, preselection cuts are applied which include
952 trigger and event requirements to reduce background contamination and the dataset
953 size. Events must contain exactly one tight lepton (no additional loose leptons),
954 the $p_T^{\ell\nu} > 75$ GeV, and there must be at least two small-R jets or one large-R jet,
955 so the event is able to pass the resolved or merged selections.

956 9.2 Trigger

957 The data were collected using the lowest unprescaled single-lepton or E_T^{miss}
958 triggers, as summarized in Table 9.1. Since the muon term is not considered in the
959 trigger E_T^{miss} calculation, the E_T^{miss} trigger is fully efficient to events with high- p_T
960 muons. For this reason, the E_T^{miss} trigger is used for events where $p_T^\mu > 150$ GeV, to
961 compensate for the poor efficiency of the single muon trigger above $p_T^\mu > 150$ GeV.

Table 9.1: The list of triggers used in the analysis.

| Data-taking period | $e\nu qq$ channel | $\mu\nu qq$ ($p_T(\mu\nu) < 150$ GeV) channel | $\mu\nu qq$ ($p_T(\mu\nu) > 150$ GeV) channel |

962 9.3 non-VBF/VBF RNN

963 To classify events as originating from non-VBF or VBF production a recursive
964 neural network (RNN [22]) is used. This approach is more powerful than a cut-
965 based classification as it improves signal efficiency and analysis sensitivity by
966 exploiting correlations between variables that the RNN learns. In particular, a
967 RNN architecture is ideal as it can handle variable numbers of jets in the events.

968 The RNN uses the four-momentum of candidate VBF jets to classify events
969 as VBF or non-VBF topologies. Sometimes jets are incorrectly reconstructed,
970 so the number of jets in the event is expected to vary across the input samples.
971 VBF candidate jets are identified by removing jets from the event that are likely
972 from $W/Z \rightarrow qq$. For the resolved regime this means removing the two leading
973 small-R jets from the VBF candidate jet list. For the merged regime this means
974 removing small-R jets separated by less than 1.0 in dR from the large-R jet. VBF
975 candidate jets are also required to be within $|\eta| < 4.5$. From the list of remaining
976 VBF candidate jets, the two highest- p_T jets are chosen.

977 The architecture of the RNN is shown in Figure 9.2. The RNN is composed
978 of Long Short Term Memory Cells (LSTM) that extract meaningful information
979 and retain it. The logic embedded in the LSTM is shown in Figure ???. LSTMs
980 are useful for VBF event classification for events with two jets, where using the
981 kinematic properties of both jets (and their correlations) will lead to more efficient
982 event classification.

983 In this RNN architecture, the VBF candidates are first passed to a masking
984 layer which checks the number of jets in the event. If there is only one jet, only one
985 vertical LSTM layer is used. The output of masking is then passed to a LSTM,
986 with a tanh activation function. The output of the LSTM is then passed to a
987 second horizontal LSTM layer (and vertical LSTM layer if there are two jets in

988 the event). Finally the output of the last LSTM cell is passed to a dense layer
989 and then to a sigmoid activation layer, leading to an overall RNN score.

990 The weights and other parameters of the network are learned by training the
991 network with HVT VBF and non-VBF signals and all simulated backgrounds over
992 200 epochs with an Adam Optimizer [14]. To prevent overfitting during training,
993 dropout is applied to RNN weights and training is truncated if the network pa-
994 rameters are unchanged after ten iterations [24]. Figure 9.4 shows the ROC curve
995 for the RNN using k-fold cross validation [20].

996 Figure 9.3 shows the RNN discriminant for backgrounds, non-VBF signals,
997 and VBF signals. The RNN score is ~ 0 for non-VBF signals and background
998 processes and ~ 1 for VBF processes. Figure 9.5 shows the limits for various signal
999 processes based on the RNN cut applied. Requiring the RNN score to be > 0.8
1000 was chosen as it provided the best analysis significance for this final state and
1001 the $\nu\nu qq$ and $\ell\ell qq$ channels, which this channel will be combined with for future
1002 publications.

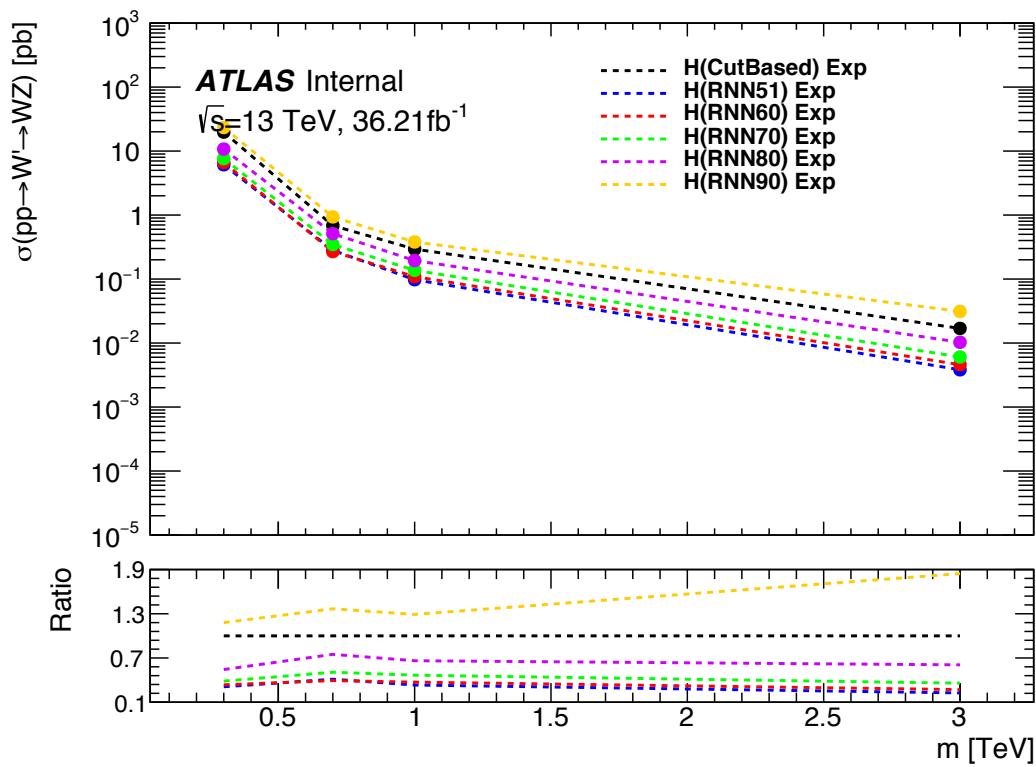

Figure 9.5: Comparison of GGF Z' limits for different RNN score selections. The bottom panel shows the ratio of the upper limits set for different RNN cuts to the cut-based analysis. In this panel smaller numbers, indicate that the expected upper limit is smaller than the cut-based analysis, which is desired.

1003 9.4 Signal Region Definitions

1004 Signal regions are constructed to be dominated by signal and used in the final
1005 likelihood fit to look for a bump in the reconstructed resonance mass distribution.
1006 Once an event is classified by the RNN, it must pass topological cuts that maximize
1007 S/\sqrt{B} . To efficiently select events with a $W \rightarrow \ell\nu$ candidate exactly one tight
1008 lepton is required and $E_T^{miss} > 100(60)$ GeV and $p_{T,\ell\nu} > 200(75)$ GeV in the
1009 merged (resolved) analysis to suppress the fake lepton backgrounds.

1010 The resonances this search probes are expected to be produced approximately
1011 at rest with the two resulting bosons produced back-to-back. For this reason,
1012 it is required that the minimum value of $(p_{T,\ell\nu}, p_{T,J})/m_{WV} > 0.35(0.25)$ for the
1013 non-VBF (VBF) category.

1014 To reduce $t\bar{t}$ contamination in the merged HVT Z' and G_{KK} analyses, events
1015 with at least one b -jet with $\Delta R > 1.0$ from the large-R jet are excluded. High
1016 purity signal regions require the D_2 and W/Z mass window cut to be passed,
1017 whereas the low purity region only requires the W/Z mass window cut to be
1018 passed. More boosted jets, are more likely to fail the D_2 cut due to track merging.
1019 Therefore, by using high and low purity regions, the signal acceptance is increased.

1020 The HVT W' resonance search uses tagged and untagged regions to minimize
1021 backgrounds and increase signal acceptance. For events to be classified as tagged
1022 the large-R jet must contain exactly two b -tagged VR jets. Untagged events must
1023 have no more than one b -tagged jet matched to the large-R jet. These selections
1024 are shown in Table 9.2.

1025 Events failing the merged selection are then re-analyzed in the resolved cat-
1026 egory. To enhance resolved signals, the event should contain two high- p_T boson
1027 candidates that are back-to-back in the ϕ as shown by the selections in Table 9.3.
1028 Again, to suppress the $t\bar{t}$ backgrounds, events are required to have no additional

Table 9.2: Summary of selection criteria used to define the signal region (SR), W +jets control region (W CR) and $t\bar{t}$ control region ($t\bar{t}$ CR) for merged 1-lepton channel.

| Selection | | SR | | W CR (WR) | | $t\bar{t}$ CR (TR1) | |
|-------------------------|---|---|------------------------------------|-----------|------|---------------------|------|
| | | HP | LP | HP | LP | HP | LP |
| $W \rightarrow \ell\nu$ | Num of Tight leptons | 1 | | | | | |
| | Num of Loose leptons | 0 | | | | | |
| | E_T^{miss} | $> 100 \text{ GeV}$ | | | | | |
| | $p_T(\ell\nu)$ | $> 200 \text{ GeV}$ | | | | | |
| $W/Z \rightarrow J$ | Num of large- R jets | ≥ 1 | | | | | |
| | D_2 cut | pass | fail | pass | fail | pass | fail |
| | W/Z mass window cut | pass | pass | fail | fail | pass | pass |
| | Numb. of associated VR track jets b -tagged | For $Z \rightarrow J$: ≤ 1 ($= 2$) for untagged (tagged) category | | | | | |
| | $\min(p_{T,\ell\nu}, p_{T,J}) / m_{WV}$ | $> 0.35(0.25)$ for DY/ggF (VBF) category | | | | | |
| | Top-quark veto | Num of b -tagged jets outside of large- R jet | 0 | ≥ 1 | | | |
| Pass VBF selection | | | no (yes) for DY/ggF (VBF) category | | | | |

1029 b -jets for the HVT Z' and G_{KK} analyses. A summary of the resolved selections
 1030 is shown in Table 9.3.

1031 The analysis cutflow in Figure 9.6 shows how the different categories are pri-
 1032 oritized. Events classified as VBF events are classified as merged high purity, low
 1033 purity or resolved signal region selections sequentially. If the event does not pass
 1034 any of these selections but passes a VBF control region selection it is classified as
 1035 a VBF CR event.

1036 If the event fails all VBF categories, it is then checked if it passes the merged
 1037 high purity, low purity or resolved signal region selections (NB: for the WZ decay
 1038 modes all the regions have tagged and untagged categories). If the event fails all
 1039 the non-VBF signal region selections, it is then kept for non-VBF control region
 1040 selections, if it passes those selections. Control region selection are discussed more
 1041 in 10.1.

1042 Overall, for the Drell-Yan HVT Z' and gluon-gluon fusion G_{KK} signals there
 1043 are 3 signal regions. For the Drell-Yan HVT W' signal there are 6 signal regions.
 1044 For VBF HVT W' and Z' signals there are 3 signal regions.

Table 9.3: The list of selection cuts in the resolved analysis for the WW and WZ signal regions (SR), $W+jets$ control region (WR) and $t\bar{t}$ control region (TR).

| cuts | | SR | W CR (WR) | $t\bar{t}$ CR (TR1) |
|-------------------------|--|--|---------------------------|-------------------------|
| $W \rightarrow \ell\nu$ | Number of Tight leptons | | 1 | |
| | Number of Loose leptons | | 0 | |
| | E_T^{miss} | | > 60 GeV | |
| | $\cancel{p}_T(\ell\nu)$ | | > 75 GeV | |
| $W/Z \rightarrow jj$ | Number of small-R jets | | ≥ 2 | |
| | Leading jet p_T | | > 60 GeV | |
| | Subleading jet p_T | | > 45 GeV | |
| | $Z \rightarrow q\bar{q}$ | $78 < m_{jj} < 105$ GeV | $50 < m_{jj} < 68$ GeV or | $50 < m_{jj} < 150$ GeV |
| | $W \rightarrow q\bar{q}$ | $68 < m_{jj} < 98$ GeV | $105 < m_{jj} < 150$ GeV | |
| Topology cuts | Num. of b -tagged jets | For $Z \rightarrow jj$: ≤ 1 ($= 2$) for untagged (tagged) category | | |
| | $\Delta\phi(j, \ell)$ | | > 1.0 | |
| | $\Delta\phi(j, E_T^{\text{miss}})$ | | > 1.0 | |
| | $\Delta\phi(j, j)$ | | < 1.5 | |
| | $\Delta\phi(\ell, E_T^{\text{miss}})$ | | < 1.5 | |
| | $\min(p_{T,\ell\nu}, p_{T,jj}) / m_{WW}$ | $> 0.35(0.25)$ for DY/ggF (VBF) category | | |
| Top veto | Number of additional b -tagged jets | 0 | | ≥ 1 |
| | Pass VBF selection | no (yes) for DY/ggF (VBF) category | | |

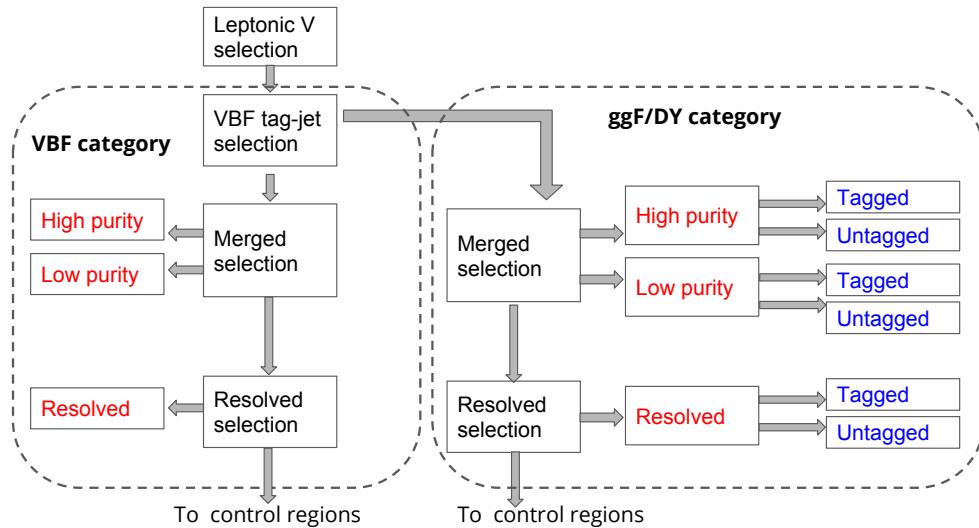

Figure 9.6: Event Categorization. Natasha write more.

1045 9.5 Selection Acceptance and Efficiency

1046 The signal acceptance is the ratio of the number of signal events selected to
 1047 the number of signal events generated at truth level, which does not account for

1048 detector effects. The signal efficiency is the ratio of the number of reconstructed
 1049 events selected and the number of truth events selected, which accounts for de-
 1050 tector effects. The expected number of signal events is given by the product of
 1051 these two quantities:

$$A \cdot \epsilon = \frac{N_{\text{events selected}}^{\text{truth}}}{N_{\text{events generated}}^{\text{truth}}} \cdot \frac{N_{\text{events selected}}^{\text{reco}}}{N_{\text{events selected}}^{\text{truth}}} = \frac{N_{\text{events selected}}^{\text{reco}}}{N_{\text{events generated}}^{\text{truth}}} \quad (9.1)$$

1052 The distributions of $A \cdot \epsilon$ as a function of the resonance mass for the different spin
 1053 models are shown in Figures 9.7 - 9.8.

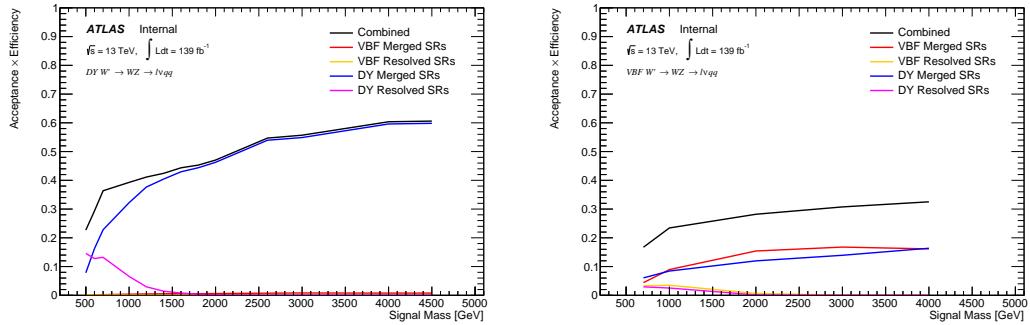

Figure 9.7: Selection acceptance times efficiency for the $W' \rightarrow WZ \rightarrow \ell\nu qq$ events from MC simulations as a function of the W' mass for Drell-Yan (left) and VBF production (right), combining the merged HP and LP signal regions of the $WV \rightarrow \ell\nu J$ selection and the resolved regions of the $WV \rightarrow \ell\nu jj$ selection. Note: the VBF selection acceptance for the DY W' is approximately zero in the left plot.

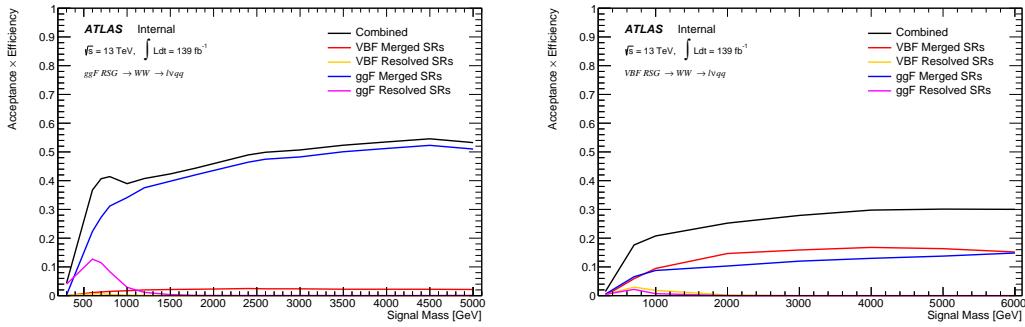

Figure 9.8: Selection acceptance times efficiency for the $G \rightarrow WW \rightarrow \ell\nu qq$ events from MC simulations as a function of the G mass for (a) Drell-Yan and (b) VBF production, combining the merged HP and LP signal regions of the $WW \rightarrow \ell\nu J$ selection and the resolved regions of the $WW \rightarrow \ell\nu jj$ selection. Note: the VBF selection acceptance for the ggF G''_{KK} is approximately zero in the left plot.

Chapter 10

1055

Background Estimate

1056 Backgrounds from VV , $t\bar{t}$, single-top, $W+\text{jets}$, $Z+\text{jets}$ are simulated as de-
1057 scribed in 7.2. The dominant backgrounds for this search are from $W+\text{jet}$ and
1058 $t\bar{t}$ processes. To more accurately model the m_{VV} distribution from these back-
1059 grounds in the SRs, control regions are constructed for each as described in 10.1.
1060 The $t\bar{t}$ and $W+\text{jets}$ control regions are called TCR and WCR, respectively. There
1061 are separate control regions for VBF and non-VBF regions as well as for each
1062 region (merged HP, merged LP, resolved). For the HVT W' search there are also
1063 tagged and untagged control regions (where tagged refers to events with two b -jets
1064 inside the large-R jet).

1065 The aforementioned backgrounds containing real leptons and are well-modeled
1066 with simulated samples. Backgrounds with fake leptons (also referred to as the
1067 multijet background) are not well-modeled with simulation. For this reason, the
1068 multijet background is extracted from data as described in 10.2.

1069 10.1 Control Regions

1070 The TCRs have the same selections as the SRs, but at least one b -jet in the
1071 event (that is not within the catchement area of the large-R jet for the merged
1072 analysis). The WCR shares the SR selections, but has different jet mass require-
1073 ments. For the merged analyses, the large-R jet must fail the W/Z tagger jet mass
1074 cut. In the resolved analyses, m_{jj} must be $50 < m_{jj} < 68$ GeV or $105 < m_{jj} < 150$
1075 GeV.

1076 The distributions for some the variables used in merged analysis (e.g. reso-
1077 nance mass, $p_T(\nu)$, $p_T(J)$) for top control regions (non-VBF and VBF HP and LP
1078 regions) are shown in Figure 10.1-10.4. The distributions for the variables used
1079 in the resolved analysis (e.g. resonance mass, $p_T(\nu)$, $p_T(j_1/j_2)$) in the TCR are
1080 shown in Figure 10.5, 10.6. In general, in these plots the simulated distributions
1081 match the data well, which is necessary to have confidence in the prediction yields
1082 in the signal regions.

1083 To more accurately model the two dominant backgrounds in this analysis,
1084 W +jets and $t\bar{t}$, control regions are constructed for each. These control regions
1085 are dominated by these processes and used to extract normalization factors in
1086 the final likelihood fit that are then used in the signal region estimates. For the
1087 $t\bar{t}$ control region the event must contain at least one such b jet. The WCR is
1088 constructed using the $m_{jj/J}$ mass window sidebands. All other backgrounds are
1089 estimated using simulation, except fake lepton backgrounds, which are derived
1090 using a data-driven method.

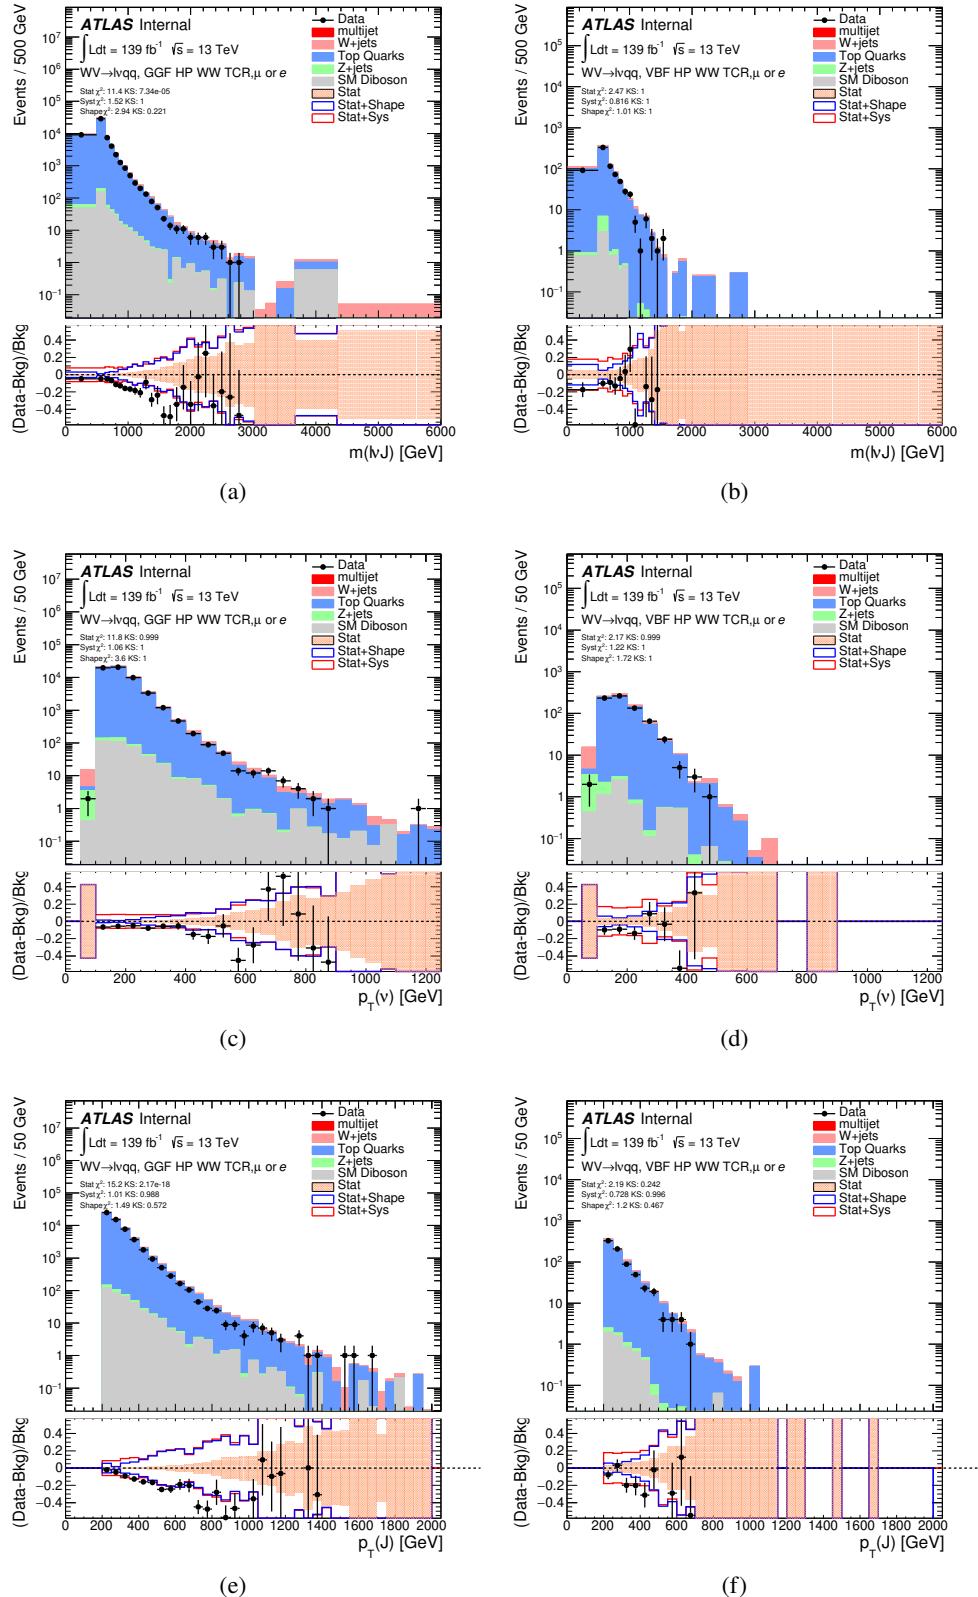

Figure 10.1: Data MC comparison for the merged WW HP TCR. The bottom panel shows the ratio of the difference between data and simulation to simulation. The red bands include the all systematic and statistical uncertainties on the background.

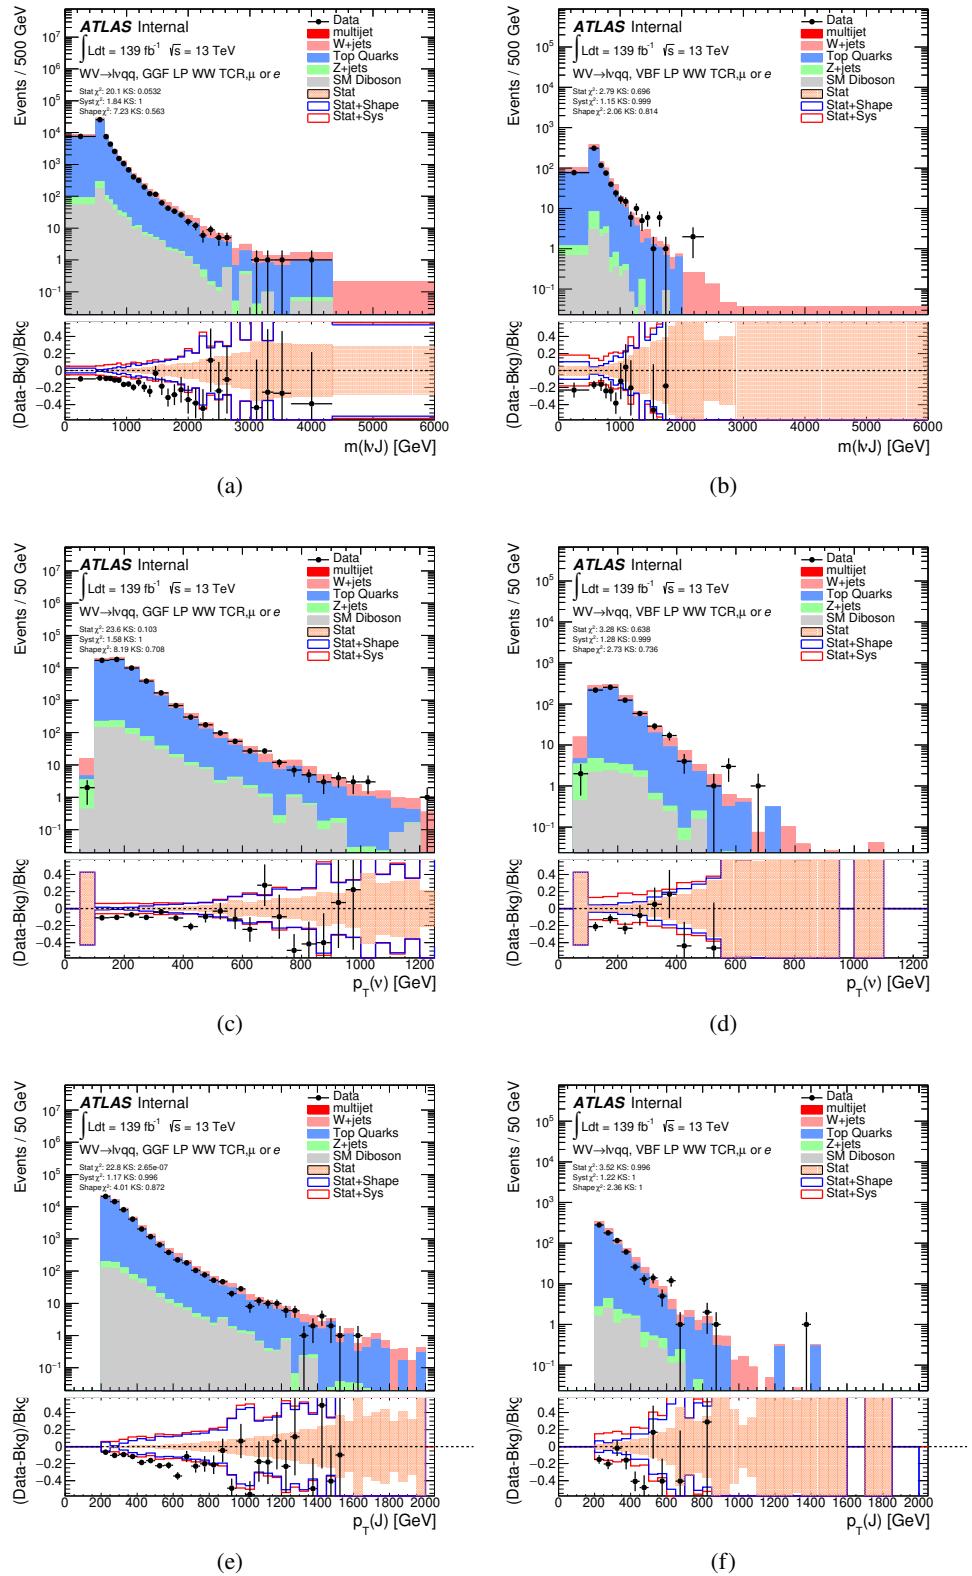

Figure 10.2: Data MC comparison for the merged WW LP TCR. The bottom panel shows the ratio of the difference between data and simulation to simulation. The red bands include the all systematic and statistical uncertainties on the background.

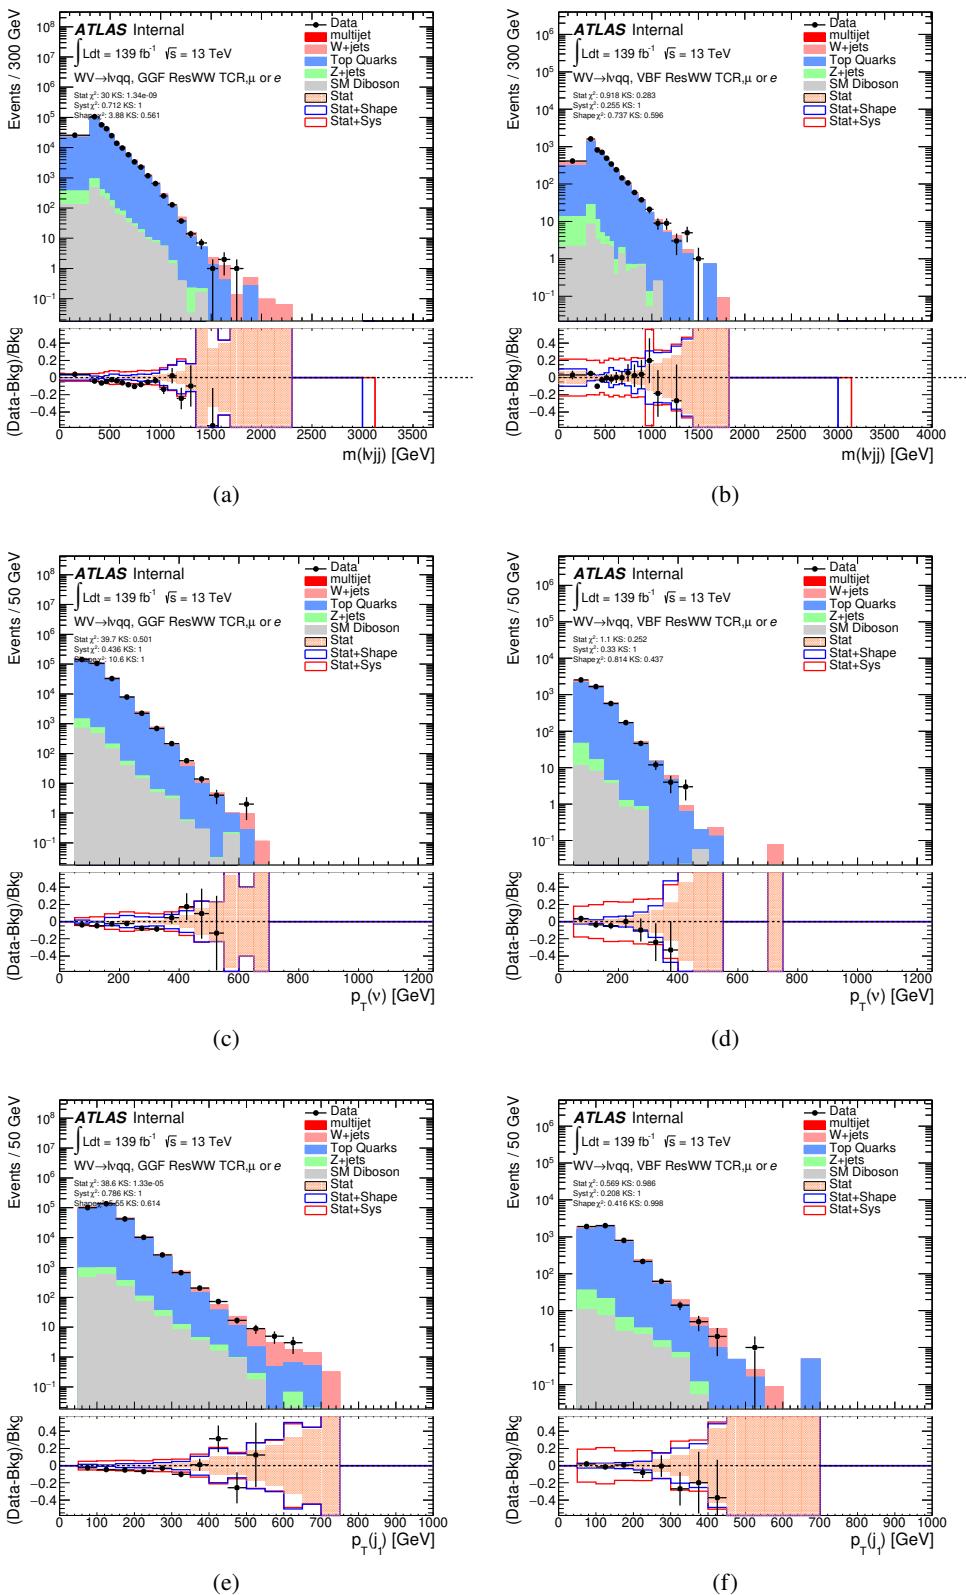

Figure 10.5: Data MC comparison for the resolved WW TCR. The bottom panel shows the ratio of the difference between data and simulation to simulation. The red bands include the all systematic and statistical uncertainties on the background.

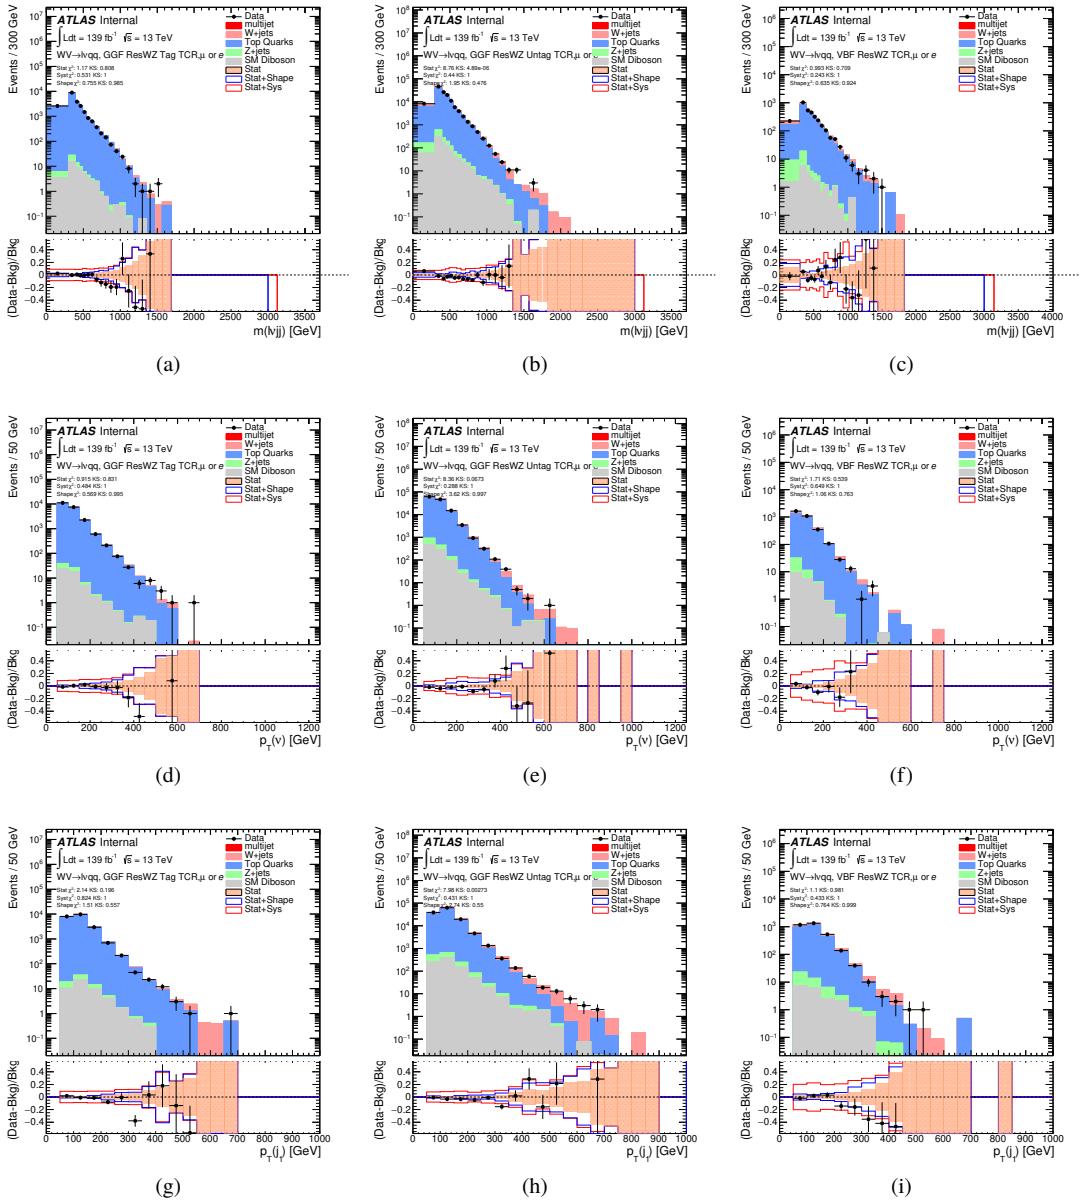

Figure 10.6: Data MC comparison for the resolved WZ TCR. The bottom panel shows the ratio of the difference between data and simulation to simulation. The red bands include the all systematic and statistical uncertainties on the background.

1091 10.2 Fake Lepton Backgrounds

1092 The fake lepton backgrounds for this search are not well-modeled with simu-
1093 lation. For this reason, this background is extracted from data. Fake electrons
1094 often arise from fake jets and converted photons while non-prompt muons usually
1095 arise from heavy flavor decay products. This predominately occurs at lower lepton
1096 momentums, and therefore is only considered in the resolved analysis.

1097 Fake electrons generally fail the electron ID criteria and fake muons fail the
1098 muon isolation requirement. Therefore, separate multijet samples are derived for
1099 the fake electron and muon samples. For each sample the m_{WV} template shape
1100 is derived for the SR and WCR selections using the same SR and WCR cuts but
1101 with inverted lepton requirements as seen in Table 10.1. NB: By inverting the
1102 lepton isolation/identification criteria the SRs and CRs are orthogonal.

1103 To derive the multijet template in a given SR, first the multijet template in
1104 the WCR is derived, called the MJCR template. This template is calculated using
1105 events that pass the WCR selection but with the inverted lepton criteria. The
1106 E_T^{miss} distribution for the MJCR is given by the difference between data and the
1107 simulated samples in the MJCR. The E_T^{miss} distribution of those events is then
1108 added to the simulated backgrounds in the WCR. The floating background and
1109 multijet normalizations of the MJCR in this region are then fit to the data. The
1110 fitted MJCR is then used as the multijet sample in the WCR.

1111 The fitted normalizations from the MJCR template are then used to construct
1112 the multijet template in the SR (MJSR). The MJSR is constructed from events
1113 that pass the SR selections but with the inverted lepton criteria. Again, the
1114 difference between the data and simulated backgrounds in this region gives MJSR
1115 template shape in m_{WV} . This shape is then scaled by the fitted normalizations
1116 from the MJCR. These fitted electron and muon muon multijet templates are then

1117 used as the multijet samples in the SRs. The normalizations of the electron and
1118 muon multijet samples are parameters in the final likelihood fit.

1119 This template method was validated using WCR and full Run 2 data. The
1120 results of the fit are shown in Table 10.2. The multijet contribution in the muon
1121 channel for $p_T^W > 150$ GeV is consistent with zero, and therefore neglected in
1122 the final fit. Applying the extracted normalization factor to MJCR in WCRs for
1123 various kinematic variables such as E_T^{miss} , W transverse mass, lepton p_T , and the
1124 invariant mass as show in Figures 10.8 -10.17. These figures show good agreement
1125 between the data and background estimate.

Table 10.1: Definitions of “inverted” leptons used in multijet control region. For the inverted muon selection, $ptvarcone30$ is given by sum of the p_T of tracks in a cone around the muon candidate divided by the muon p_T . The size of the cone, δR used is $10\text{GeV}/p_T^\mu$ or 0.3, whichever is smaller. So, as the p_T of the muon increases, the cone size used decreases. This is useful as more boosted muons are more likely to be produced in dense environments and using a smaller cone size more accurately determines the quality of the muon.

| | Criterion | signal lepton | inverted lepton |
|----------|-----------------|---------------------------|--|

Table 10.2: Fit validation result in WCRs for 2015+16 data. The fit is done in various WCRs, in order to obtain the corresponding scale factors for MJ templates: ggF resolved WCR for the $WW \rightarrow lvqq$ selection, ggF resolved untagged WCR for the $WZ \rightarrow lvqq$ selection, ggF resolved tagged WCR for the $WZ \rightarrow lvqq$ selection, VBF resolved WCR for the $WW \rightarrow lvqq$ selection, and VBF resolved WCR for the $WZ \rightarrow lvqq$ selection. Post-fit event yields for electroweak processes and MJ contributions are shown. The SF column shows the corresponding normalization scale factors for electroweak processes from the fit. R.U. stands for relative uncertainty.

₁₁₂₇ **Chapter 11**

₁₁₂₈ **Systematic Uncertainties**

₁₁₂₉ This section describes the sources of systematic uncertainties of the m_{WV} dis-
₁₁₃₀ tribution. These uncertainties are divided into experimental and modeling un-
₁₁₃₁ certainties. Each systematic uncertainty is treated as a nuisance parameter in
₁₁₃₂ the final likelihood fit. The dominant systematics in this analysis arise from jet
₁₁₃₃ reconstruction and the generator choice for the $V + \text{jets}$ backgrounds.

₁₁₃₄ **11.1 Experimental Systematics**

₁₁₃₅ The uncertainty on the integrated luminosity of the dataset used is 1.7% and
₁₁₃₆ a systematic in the final fit. This uncertainty was calculated using $x - y$ beam
₁₁₃₇ separation scans [natasha ref P55].

₁₁₃₈ Another source of systematic uncertainty is assigned to the pileup modeling in
₁₁₃₉ MC samples. This ensures simulated detector response and particle reconstruction
₁₁₄₀ conditions are as similar as possible. The distribution of the average number of
₁₁₄₁ interactions per bunch crossing applied to simulation is called the μ profile. The
₁₁₄₂ pileup modeling uncertainty is accounted for by re-weighting simulated events so
₁₁₄₃ the average number of interactions per bunch crossing varies within its uncertainty

1144 due to systematics from vertex reconstruction [cite ATL-COM-SOFT-2015-119].

1145 The associated re-weighting factors are propagated through the entire analysis

1146 chain to construct a systematic uncertainty on m_{VV} .

1147 The single-lepton and E_T^{miss} triggers used are not fully efficient, so scale factors

1148 are applied to simulation to more accurately model the data. These scale factors

1149 are given by the ratio of the distribution of offline objects before trigger selection

1150 and after trigger selection. The associated uncertainty on these scale factors are

1151 used in the final fit.

1152 Uncertainties on small-R jet energy scale and resolution are measured in-situ

1153 by calculating the response between data and simulation. This analysis uses a

1154 reduced set of JES and JER uncertainties (totaling 30 and 8 systematics, respec-

1155 tively). This reduced set of systematics is calculated using a principal component

1156 analysis, yielding largely uncorrelated independent systematics. These uncertain-

1157 ties on jet energy scale and resolution (JES and JER, respectively) account for the

1158 dependence on p_T , η , μ , flavor response and global sequential corrections. System-

1159 atic uncertainties associated with b -tagging are also considered. These systematics

1160 are evaluated as uncertainties on a scale factor which accounts for the difference

1161 in b -tagging efficiencies in data and MC, and the flavor dependence (between b,

1162 c, and light jets).

1163 The uncertainty on the p_T scale of the large-R jets is determined by comparing

1164 the jet's p_T^{calo} to p_T^{track} in di-jet simulation and data. In addition to this uncertain-

1165 ties from tracking, modeling (Pythia vs Herwig), and statistical constraints are

1166 also calculated. The large-R jet p_T resolution is given by smearing the jet p_T with

1167 a Gaussian with a 2% width.

1168 The W/Z tagging efficiency scale factor is estimated by comparing the tagging

1169 efficiency in simulation with that in data for four regions of the W/Z tagger (D_2

fail, m_J fail; D_2 pass, m_J fail; D_2 fail, m_J pass; D_2 pass, m_J pass). (Additionally, separate scale factors are determined for events with large-R jets from W bosons and top backgrounds.) A simultaneous template fit is used to fit the signal jets (jets initiated by W/Z bosons or top quarks) and background jets (all other jets from the simulated backgrounds) to the data in the four regions using the m_J distributions. The scale factor for a given region is then given by:

$$SF = \frac{\epsilon_{data}^{region}}{\epsilon_{MC}^{region}} = \frac{\frac{N_{fitted-signal}^{region}}{N_{all-regions}^{fitted-signal}}}{\frac{N_{signal}^{region}}{N_{all-regions}^{signal}}} \quad (11.1)$$

The effects of experimental and theoretical uncertainties on the efficiency scale factor are determined by taking the ratio of efficiencies in data and simulation. By taking this ratio the uncertainties not arising for jet mass and D_2 cancel.

Lepton identification, reconstruction, isolation systematic uncertainties are determined by reconstructing the Z mass peak with a tag and probe method. The lepton energy and momentum scales are also measured with the Z mass peak.

As E_T^{miss} is calculated using all the physics objects in the event, all those objects associated errors result in an uncertainty on E_T^{miss} . Additionally, the unassociated tracks used to construct E_T^{miss} contribute to the uncertainty on E_T^{miss} .

11.2 Theory Systematics

Theoretical uncertainties for signal and background processes arise from uncertainties in the parameters used in Monte Carlo simulation. In particular for the $t\bar{t}$, $W/Z+jets$, diboson backgrounds and signal samples, the QCD scale, PDF, generator and hadronization uncertainties were evaluated. To assess the QCD scale uncertainty the renormalization and factorization scales were scaled up and

1191 down by a factor of two at the event generation stage of sample production. Un-
1192 certainties due to the choice of the parton distribution functions were evaluated by
1193 re-weighting samples from the nominal PDF to a set of error PDFs which account
1194 for the uncertainty of the fits used to produce the PDF set. In addition to this,
1195 samples are re-weighted to different PDF sets to account for the arbitrariness of
1196 the PDF choice. The difference between the m_{WV} distributions using different
1197 event generators is assessed by comparing samples generated with different gen-
1198 erators. Similarly, the uncertainty in hadronization models is accounted for by
1199 comparing samples created using different hadronization models (e.g. $t\bar{t}$ Powheg
1200 is compared to AMC@NLO, $W + jets$ compares Sherpa and MadGraph+Pythia
1201 samples). Figures 11.1 - 11.8 show the impact of these uncertainties on the $t\bar{t}$ and
1202 $W/Z + jets$ backgrounds. Additionally, contributions to the diboson background
1203 for the VBF analysis were found to be small and were accounted for by including
1204 a 5(10)% systematic in the diboson normalization in the final fit.

1205 The normalization of the $t\bar{t}$ and $W+jets$ processes impact the multijet tem-
1206 plate shape. The impact of these normalizations was assessed by including a shape
1207 systematic on the multijet background from varying the $t\bar{t}$ and $W+jets$ normal-
1208 ization factors. The overall normalization of the template is systematic in the
1209 final likelihood fit (account for other systematic effects on the template).

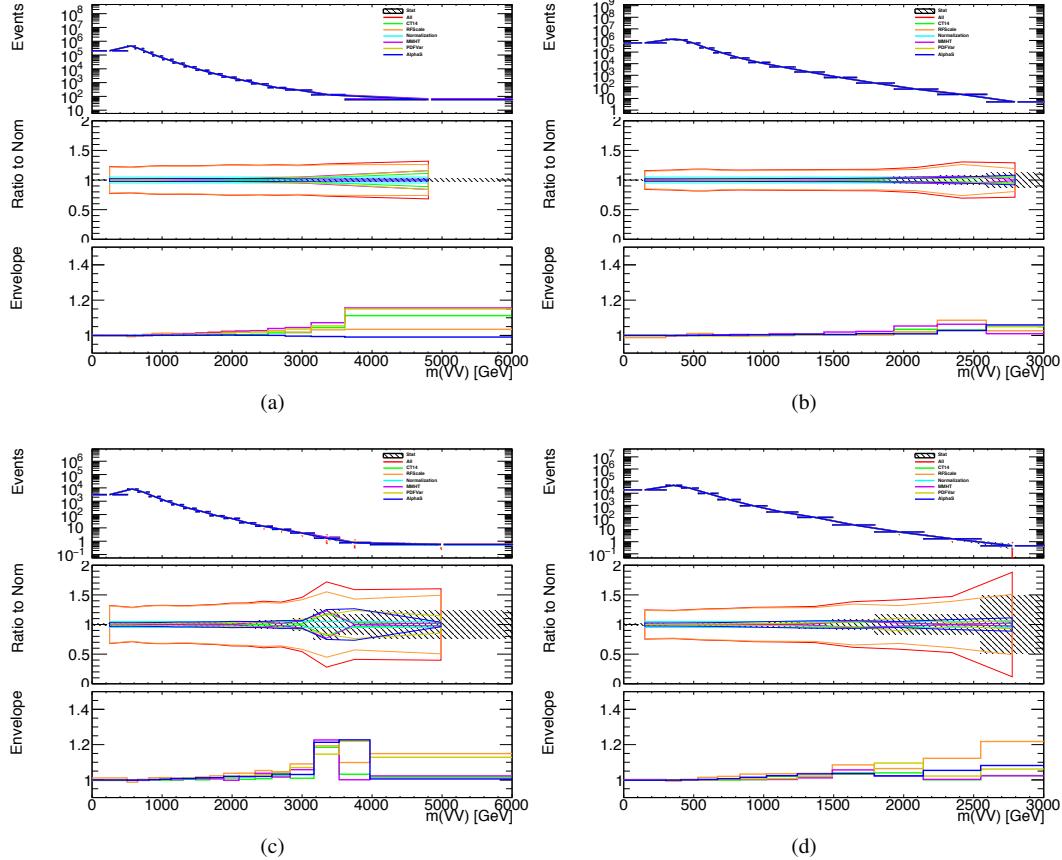

Figure 11.1: The $W/Z + \text{jet}$ systematics for the a) Merged ggF, b) Resolved ggF, c) Merged VBF, and d) Resolved VBF regions. The top subplot shows the nominal and variation distributions/bands, the middle shows the ratio of the two, and the final shows just the shape of the envelope (the final uncertainty).

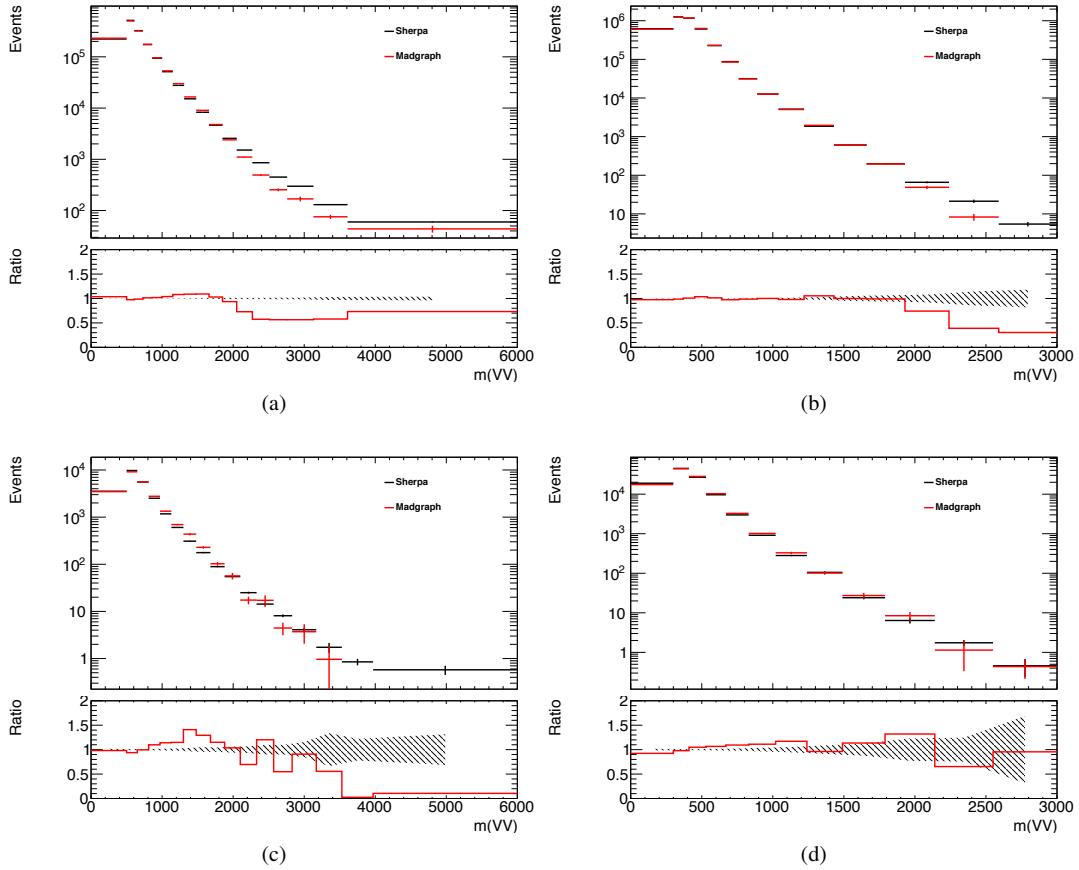

Figure 11.2: The two-point generator comparison between Sherpa and MadGraph for the $W/Z + \text{jet}$ samples in the a) Merged ggF, b) Resolved ggF, c) Merged VBF, and d) Resolved VBF regions. The normalization of the Madgraph sample is set to the Sherpa value to consider only shape effects. The bottom inset shows the ratio of the two.

₁₂₁₀ **Chapter 12**

₁₂₁₁ **Statistical Analysis**

₁₂₁₂ To determine the compatibility of the data collected with the proposed reso-
₁₂₁₃ nances a statistical procedure based on a likelihood function is used. This test
₁₂₁₄ compares the distribution of m_{WV} for the background only hypothesis with the
₁₂₁₅ background and signal hypothesis (see Figures 13.5 - 13.9 for m_{WV} SR distribu-
₁₂₁₆ tions). A discovery test is used to measure the compatibility of the observed data
₁₂₁₇ with the background only hypothesis. If the observed data are sufficiently incom-
₁₂₁₈ patible with the background only hypothesis, this could indicate a discovery. In
₁₂₁₉ the absence of discovery, upper limits on the signal strength parameter, μ , are as-
₁₂₂₀ sessed using the CLs method. For signal masses below 500GeV only the resolved
₁₂₂₁ analysis is used, as the merged analysis is not applicable for such small resonance
₁₂₂₂ masses. Similarly, it is unlikely that the two jets from the hadronically decaying
₁₂₂₃ boson will be well separated for signal masses exceeding 1 TeV. Therefore, only
₁₂₂₄ the merged analysis is used above 1TeV. For signal masses between 500 - 1000
₁₂₂₅ GeV the merged and resolved analyses are combined for the signal production
₁₂₂₆ mode considered.

12.1 Likelihood Function Definition

1227 The likelihood function is product of Poisson probabilities over all m_{WV} bins
1229 and the associated systematics:

$$\mathcal{L}(\mu, \boldsymbol{\theta}) = \prod_c \prod_i \frac{(\mu s_{ci}(\boldsymbol{\theta}) + b_{ci}(\boldsymbol{\theta}))^{n_{ci}}}{n_{ci}!} e^{-(\mu s_{ci}(\boldsymbol{\theta}) + b_{ci}(\boldsymbol{\theta}))} \prod_k (\theta'_k | \theta_k) \quad (12.1)$$

1230 Here c are the analysis channels (e.g. merged SRs and CRs and resolved SRs
1231 and CRs) considered and i runs over all the m_{WV} bins used in the fit. The
1232 signal strength parameter, μ , multiplies the expected signal yield in each anal-
1233 ysis bin, s_{ci} . The background content for channel c and bin i is given by b_{ci} .
1234 The dependence of signal and background predictions on systematic uncertain-
1235 ties is described by the aforementioned set of nuisance parameters $\boldsymbol{\theta}$, which are
1236 parameterized by Gaussian or log-normal priors denoted here as θ_k . Statistical
1237 uncertainties of the simulated bin contents are also included as systematic un-
1238 certainties. Most systematics are correlated among all the analysis regions and
1239 considered to be independent from each other. The validity of this assumption is
1240 checked by evaluating the covariance of nuisance parameters.

12.2 Fit Configuration

1242 The binning of m_{WV} in signal regions for the likelihood fit is determined by the
1243 statistical uncertainty of signal mass width. For each signal mass point, the signal
1244 mass resolution is given by the fitted Gaussian width in simulate of m_{WV} . The
1245 fitted signal widths are then fit to a line to give a parameterized signal mass width,
1246 as shown in Figures 12.1 and 12.2. Bin widths are set first to this parameterized
1247 signal mass resolution. Then if the statistical uncertainty of the data or simulated

1248 background is more than 50%, bins are merged until the statistical uncertainty is
1249 less than 50%. All control regions contain only a single bin.

1250 For this analysis, each signal model is fit in the Merged and Resolved chan-
1251 nels for the relevant signal production mode simultaneously. The $W + \text{jets}$ and $t\bar{t}$
1252 normalizations are given by the best fit values in the overall fit and these fitted
1253 normalizations are then applied to those backgrounds in the SRs, as mentioned
1254 previously.

1255 The m_{VV} distributions for a given systematic may contain unphysically large
1256 fluctuations due to m_{VV} bins with few events. This can lead to artificial pulls and
1257 constraints in the fit. To remove such issues a multi-step smoothing procedure is
1258 applied to all systematic variation distributions. First, distributions are rebinned
1259 until the statistical error per bin is at least 5%. Next all local extrema are identi-
1260 fied. The bins around smallest extrema are iteratively merged until only four local
1261 extrema remain. Then distributions are rebinned so that statistical uncertainties
1262 in each bin are $< 5\%$.

1263 For some systematics, up and down variations may be in the same direction
1264 with respect to the nominal distributions. This causes the variations to not cover
1265 the nominal choice, and the interpretation of the confidence interval is skewed as
1266 the nominal distribution should be bracketed by the up and down variations. This
1267 asymmetry may also lead to unconstrained systematics in the fit. To handle such
1268 asymmetric systematics, if the up and down variation for a given systematic are in
1269 the same direction for at least three m_{VV} bins the variation is averaged for those
1270 bins. The averaging procedure replaces bin-by-bin the up and down variation bins
1271 by $b_{\pm}^{new} = b_{nom} \pm \frac{|b_+ - b_-|}{2}$, where b_{nom} is the nominal bin content and b_{\pm} are the
1272 original up and down variation bin content. The same procedure is also applied to
1273 any variations where the integral of the difference between the up/down variation

1274 and the nominal distribution is twice that of the other down/up variation, further
 1275 ensuring variations are symmetric around the nominal distribution.

1276 Finally, systematics that have a negligible effect on the m_{WW} distribution are
 1277 not considered in the fit. Shape systematics where no bin in the variational dis-
 1278 tribution deviates more than 1% from the nominal distribution (after normalizing
 1279 all histograms to the nominal) are not included in the fit. Also, statistical bin
 1280 uncertainties < 1% are ignored.

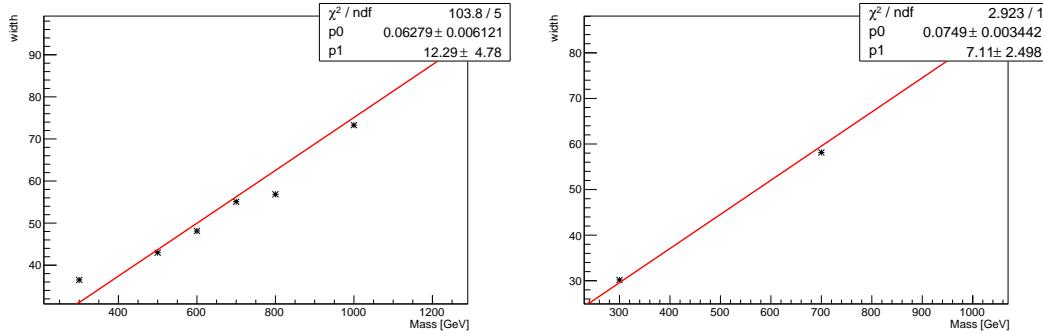

Figure 12.1: The HVT signal mass resolution as a function of mass fit with a straight line in the Resolved ggF region (left) and VBF (right) region.

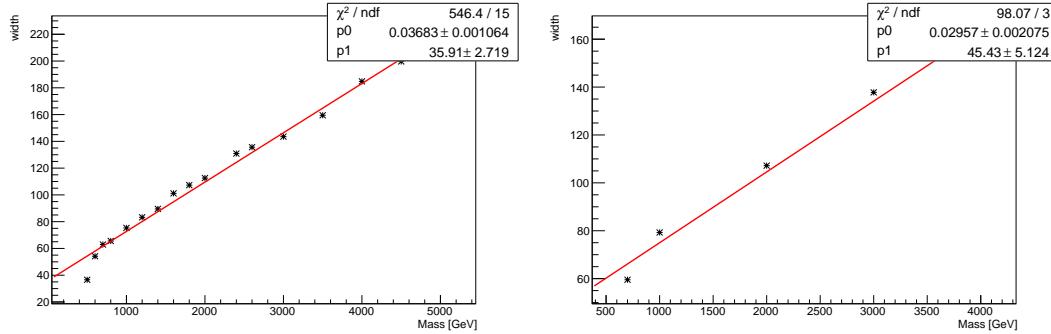

Figure 12.2: The HVT signal mass resolution as a function of mass fit with a straight line in the Merged ggF region (left) and VBF (right) region.

1281 **12.3 Best Fit μ**

1282 The best fit signal strength parameter is denoted by $\hat{\mu}$ and calculated by
1283 maximizing the likelihood function over the entire m_{WV} distribution with respect
1284 to all systematics and μ . The corresponding set of systematics that maximize
1285 the likelihood are given by $\hat{\boldsymbol{\theta}}$. The first term in the likelihood is maximized
1286 when the expected number of signal and background events over all m_{WV} bins is
1287 equal to the number of events in data ($n_{ci} = \mu s_{ci} + b_{ci}$) . Thus, by maximizing
1288 the likelihood, the fit determines value of μ and $\boldsymbol{\theta}$ that give the best agreement
1289 between expected and measured event yields. The second term in the likelihood
1290 is a penalty term which decreases the likelihood when systematics are shifted
1291 from their nominal values. This prevents the fit from profiling (unexpectedly)
1292 constraining or shifting the fitted value of a systematic far from its nominal value)
1293 systematics in unphysical ways to maximize the likelihood. The uncertainty on
1294 μ is calculated by varying μ up and down until the natural log of the likelihood
1295 function shifts by one-half.

1296 **12.4 Discovery Test**

1297 To determine if the observed dataset is consistent with tested signal model a
1298 likelihood ratio is constructed:

$$\lambda(\mu) = \frac{\mathcal{L}(\mu, \hat{\boldsymbol{\theta}}_\mu)}{\mathcal{L}(\hat{\mu}, \hat{\boldsymbol{\theta}})} \quad (12.2)$$

1299 The denominator in this equation is the maximized value of \mathcal{L} over all system-
1300 atics and μ . The numerator is the maximized likelihood over all systematics for
1301 a given μ value, where the maximized systematics are given by $\hat{\boldsymbol{\theta}}_\mu$. To test for
1302 the existence of signal the observed dataset the null hypothesis (H_0) is defined as

1303 the background only hypothesis and the alternate hypothesis includes signal and
 1304 background (H_1). This test quantifies the compatibility of observed data with
 1305 H_0 by calculating a p-value representing the probability of observing data as dis-
 1306 crepant or more than the observed data under the H_0 . The test statistic used to
 1307 calculate this p-value is given by (r_0):

$$r_0 = \begin{cases} -2 \ln \lambda(0), \hat{\mu} > 0 \\ +2 \ln \lambda(0), \hat{\mu} < 0 \end{cases} \quad (12.3)$$

1308 The expected distribution of the the test statistic under H_0 ($f(r_0|0)$) is used
 1309 to calculate the p-value:

$$p_0 = \int_{r_0,obs}^{\infty} f(r_0|0) dr_0 \quad (12.4)$$

1310 Small p-values indicate the observed data is poorly described by H_0 . This
 1311 equivalent Z-score of a given p-value is usually used to further quantify the agree-
 1312 ment between the observed data and H_0 . The Z-score is given by the number of
 1313 standard deviations away from the mean of a Gaussian distribution, the integral
 1314 of the upper tail of the distribution would equal the p-value. Mathematically:

$$Z = \Phi^{-1}(1 - p_0) \quad (12.5)$$

1315 where Φ is the Gaussian cumulative distribution function. The statistical
 1316 significance of these tests are expressed as the Z -score. In particle physics, 3σ is
 1317 considered evidence for new phenomena and 5σ is the threshold for discovery.

1318 12.5 Exclusion Limits

1319 In the absence of discovery, upper limits on the signal strength, μ are set using
 1320 the CLs method [cite P60]. The test statistic for this test, q_μ , is constructed as:

$$\tilde{\lambda}_\mu = \begin{cases} \frac{\mathcal{L}(\mu, \hat{\theta}_\mu)}{\mathcal{L}(\hat{\mu}, \hat{\theta})}, \hat{\mu} > 0 \\ \frac{\mathcal{L}(\mu, \hat{\theta}_\mu)}{\mathcal{L}(0, \hat{\theta}_0)}, \hat{\mu} < 0 \end{cases} \quad (12.6)$$

$$\tilde{q}_\mu = \begin{cases} -2 \ln \tilde{\lambda}(\mu), \hat{\mu} < \mu \\ +2 \ln \tilde{\lambda}(\mu), \hat{\mu} > \mu \end{cases} \quad (12.7)$$

1321 As defined, larger values of q_μ correspond to increasing incompatibility between
 1322 the observed data and the background + signal hypothesis. The observed value
 1323 of the test statistic, $q_{\mu, obs}$, is then compared to its expected distribution, f , to
 1324 calculate p-values to assess the likelihood of the background+signal hypothesis.
 1325 Using these distributions, CL_s values are computed as:

$$CL_{s+b} = \int_{q_{\mu, obs}}^{\infty} f(q_\mu | \mu) dq_\mu \quad (12.8)$$

$$CL_b = \int_{q_0^{obs}}^{\infty} f(q_\mu | \mu = 0) dq_\mu \quad (12.9)$$

$$CL_s = \frac{CL_{s+b}}{CL_b} \quad (12.10)$$

1328 CL_{s+b} is the p-value for the signal + background hypothesis and CL_b is the
 1329 p-value for the background only hypothesis. The CL_s value is interpreted as
 1330 the probability to observe the background + signal hypothesis normalized to the
 1331 probability of background-only hypothesis. Normalizing by CL_b prevents setting
 1332 artificially strong exclusion limits due to downward fluctuations in data.

1333 For a given signal hypothesis, μ values are scanned simultaneously over all

₁₃₃₄ m_{WV} bins to find the μ value that yields $CL_s=0.05$, meaning the likelihood of
₁₃₃₅ finding data more incompatible with the signal+background hypothesis (relative
₁₃₃₆ to the background only hypothesis) is 5%. The 95% upper limit on the cross
₁₃₃₇ section is then calculated as the product of the μ value found, branching ratio,
₁₃₃₈ and theory cross section.

₁₃₃₉ **Chapter 13**

₁₃₄₀ **Results**

₁₃₄₁ **13.1 Expected and Measured Yields**

₁₃₄₂ The yield tables for the four analysis regions are shown in Tables ?? - ??.

₁₃₄₃ The fitted background normalizations are shown in Tables ??-??. The control

₁₃₄₄ region $m_{\ell\nu qq}$ distributions are shown in Figures 13.1 - 13.4. The signal region

₁₃₄₅ $m_{\ell\nu qq}$ distributions are shown in Figures 13.5 - ??.

1346 13.2 Systematic Profiling and Correlations

1347 The ranked systematics and their fitted values are shown for the different
 1348 analysis regions in Figure 13.10 - 13.12. Note that background normalizations for
 1349 $W + \text{jets}$ and $t\bar{t}$ are left free to float in the fit. This means the nominal normal-
 1350 ization values are at one and the uncertainties are not shown in the ranked plots.
 1351 Overall, systematics are not pulled outside their uncertainties, especially nuisance
 1352 parameters that affect the fitted μ value most significantly.

1353 The correlation between systematics are shown in Figures ???. Correlations
 1354 between background normalization are expected. The remaining systematic cor-
 1355 relations are not very strong or unexpected.

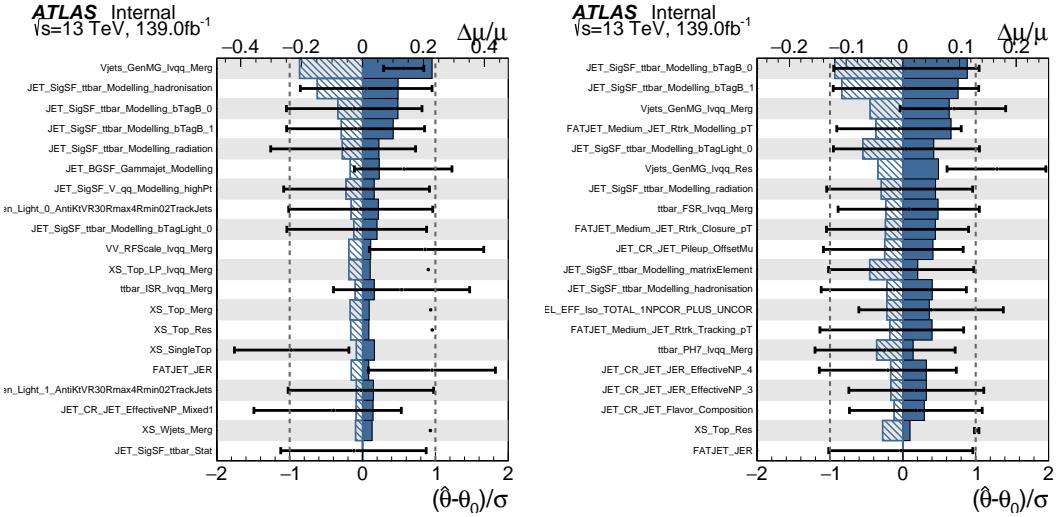

Figure 13.10: Ranked systematics and their fitted values for WW DY (right) and VBF (left) selections.

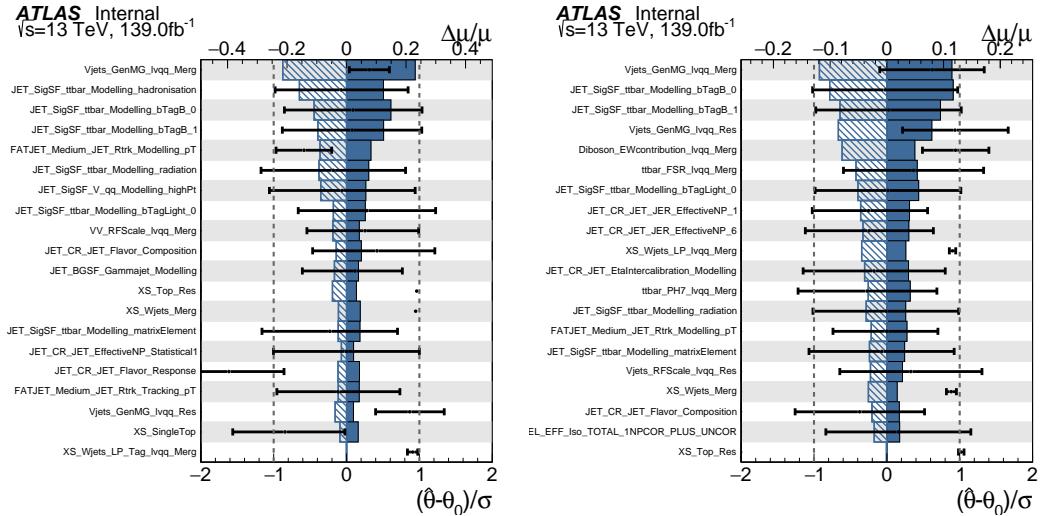

Figure 13.11: Ranked systematics and their fitted values for WZ DY (right) and VBF (left) selections.

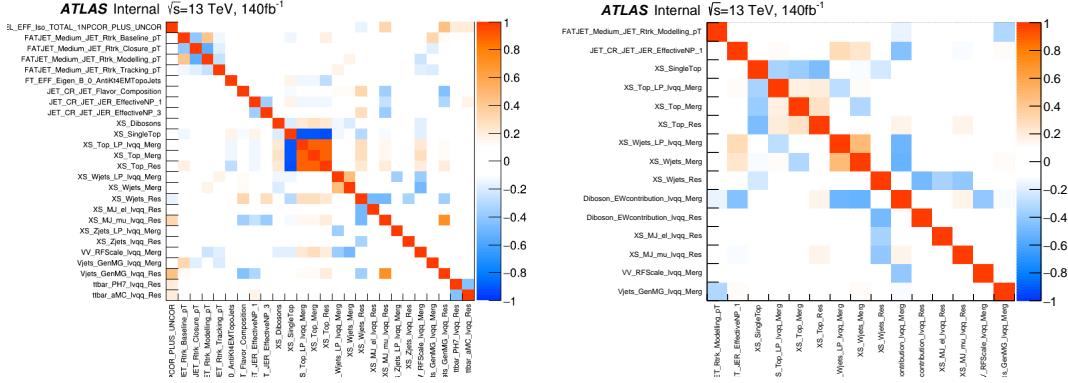

Figure 13.12: Correlations between systematics for WW DY (right) and VBF (left) selections.

13.3 Discovery Tests

To test for the existence of signal in the observed dataset, the discovery tests discussed earlier are used to calculate p-values as a function of resonance mass. The results of these tests are shown in Figures 13.13 - 13.17. Across the different DY signals the largest excesses are $\sim 2.2\sigma$ at 600 GeV and 1.8σ at 2 TeV. The largest excesses for VBF signals are $< 2.5\sigma$ at for 1 TeV resonances. As these deviations do not constitute discoveries, upper limits on μ are calculated.

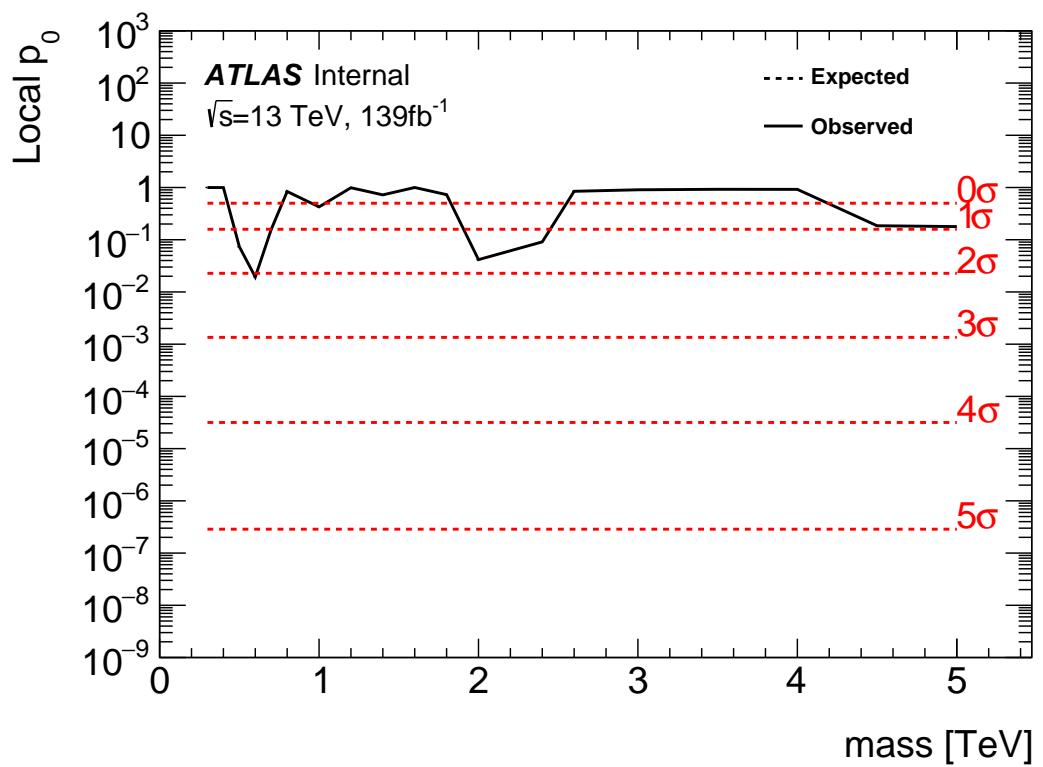

Figure 13.13: These plots show the measured p_0 value as a function of resonance mass for HVT Z' DY production.

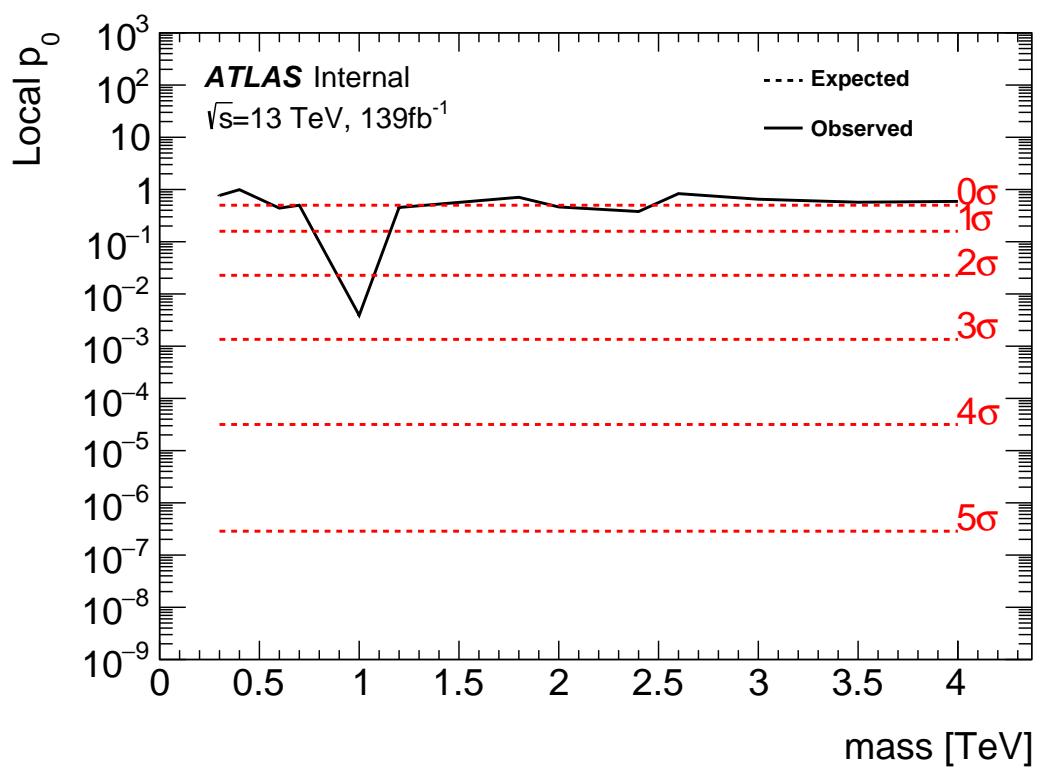

Figure 13.14: These plots show the measured p_0 value as a function of resonance mass for HVT Z' VBF production.

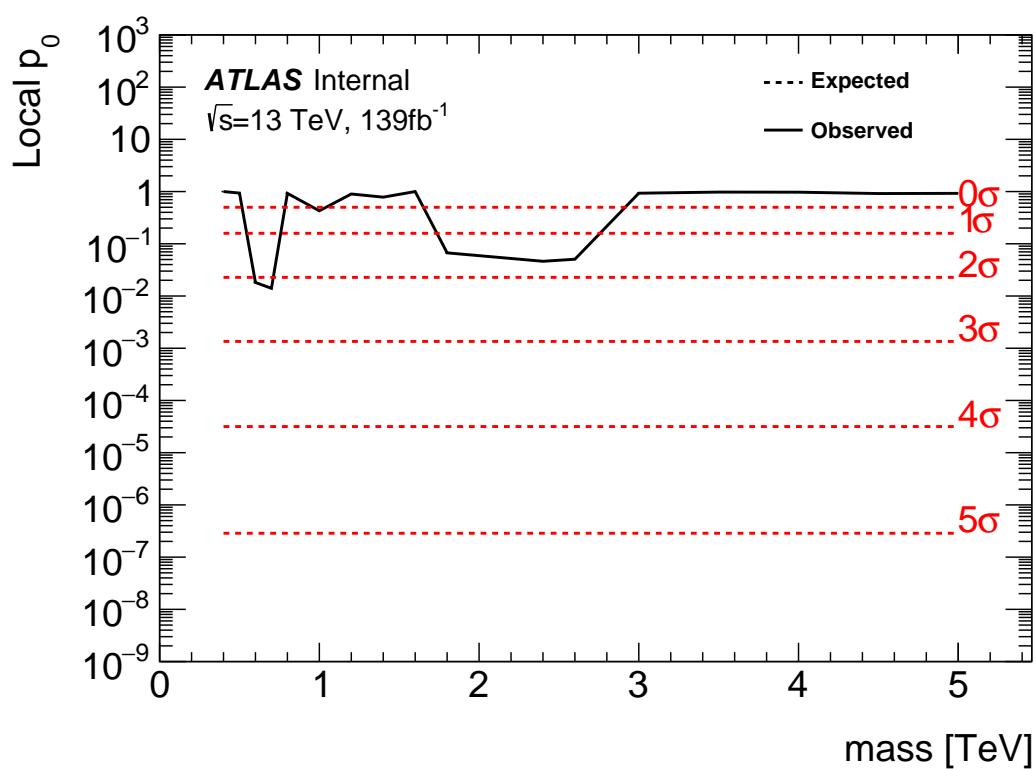

Figure 13.15: These plots show the measured p_0 value as a function of resonance mass for HVT W' DY production.

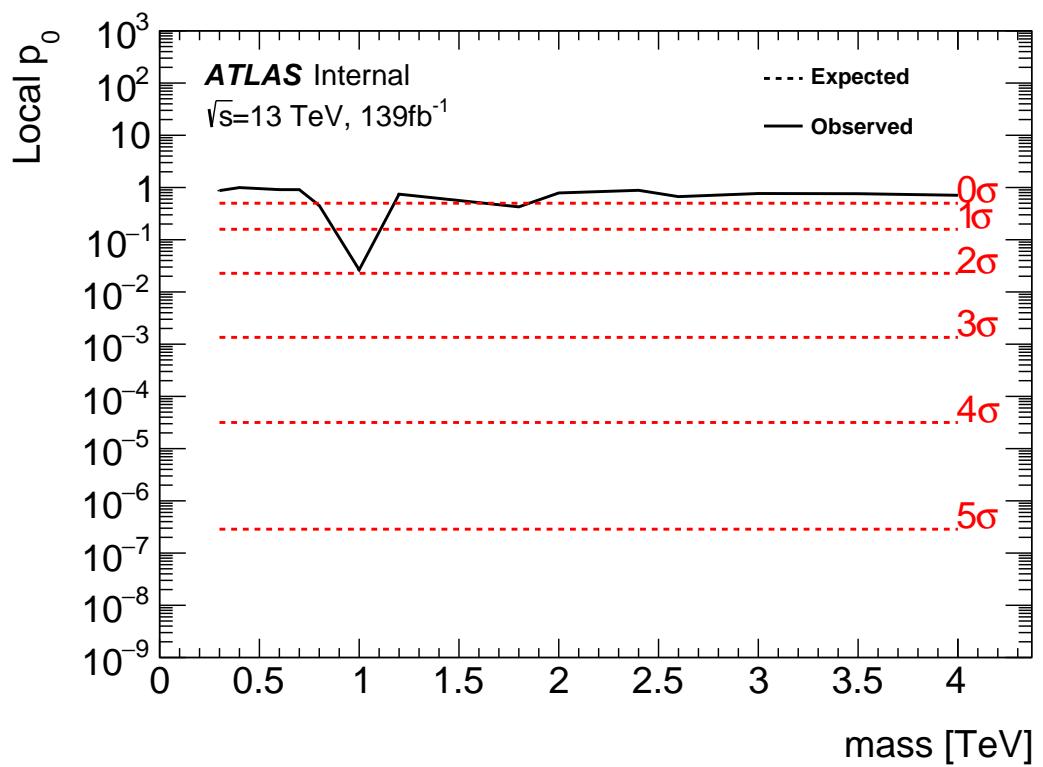

Figure 13.16: These plots show the measured p_0 value as a function of resonance mass for HVT W' VBF production.

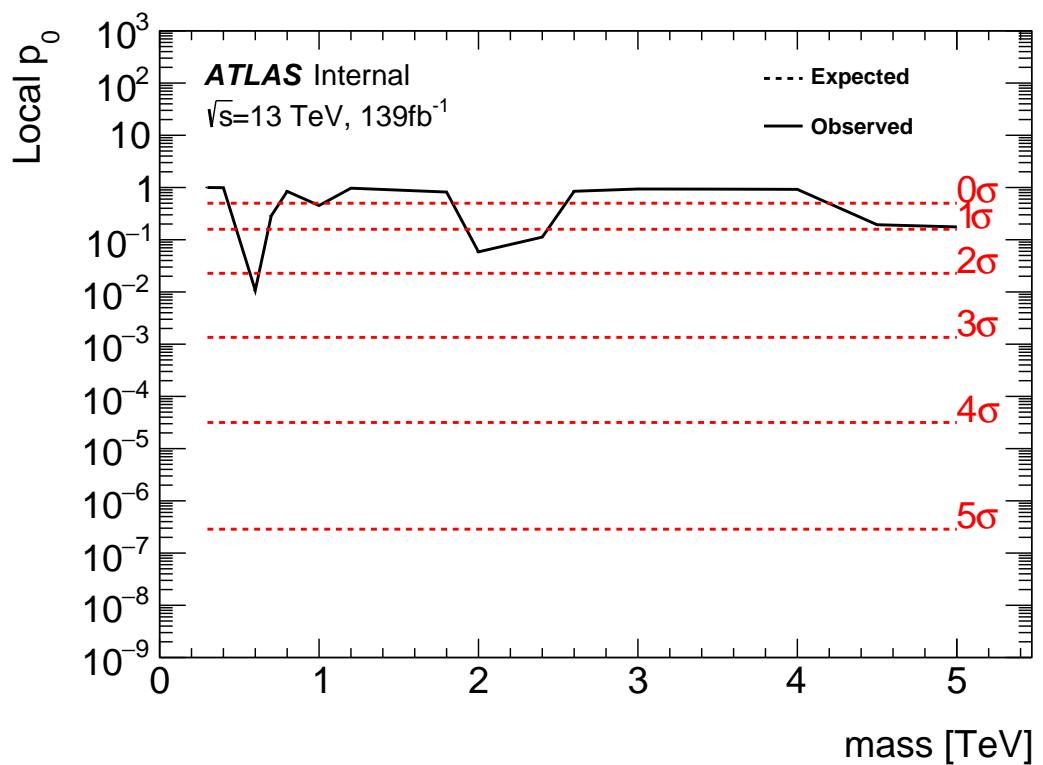

Figure 13.17: These plots show the measured p_0 value as a function of resonance mass for the RS Graviton DY production.

1363 13.4 Limits

1364 Using the exclusion limits tests discussed previously, exclusion limits are set
 1365 on μ and consequently cross-sections for different signal models. Exclusion limits
 1366 for the models considered are shown in Figure 13.18 - 13.20. These plots show the
 1367 theory cross section for a given resonance to decay to WW/WZ . Also, an Asimov
 1368 dataset is used to calculate the limits that could be set for the background only
 1369 hypothesis with the associated errors on this predictions. Finally, the observed
 1370 limits are shown in black. All signal mass where the theory prediction is less than
 1371 the observed prediction are excluded at the 95% confidence level. These limits
 1372 shown exclude HVT Model A $W' < 3.4\text{TeV}$ and $Z' < 3.3\text{ TeV}$ and Model B W'
 1373 $< 3.7\text{ TeV}$ and $Z' < 3.7\text{ TeV}$. Randall Sundrum Gravitons are excluded for masses
 1374 below 1.6TeV .

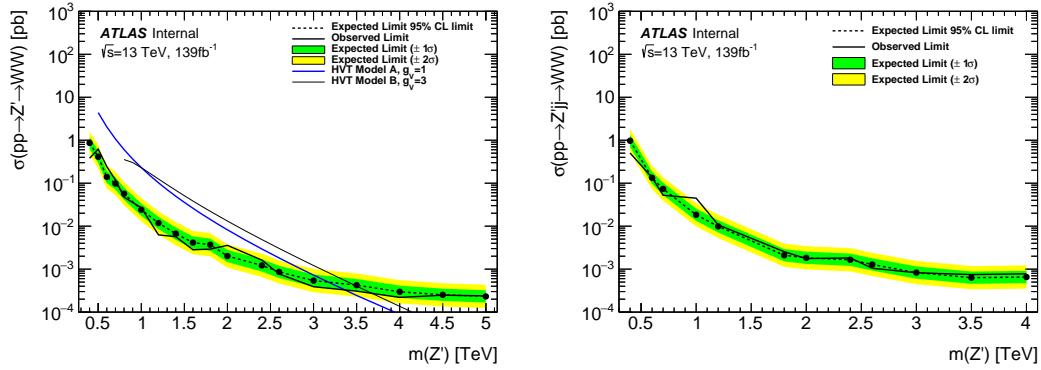

Figure 13.18: This figure shows theory, expected and observed limits for HVT W' DY (left) and VBF (right) production.

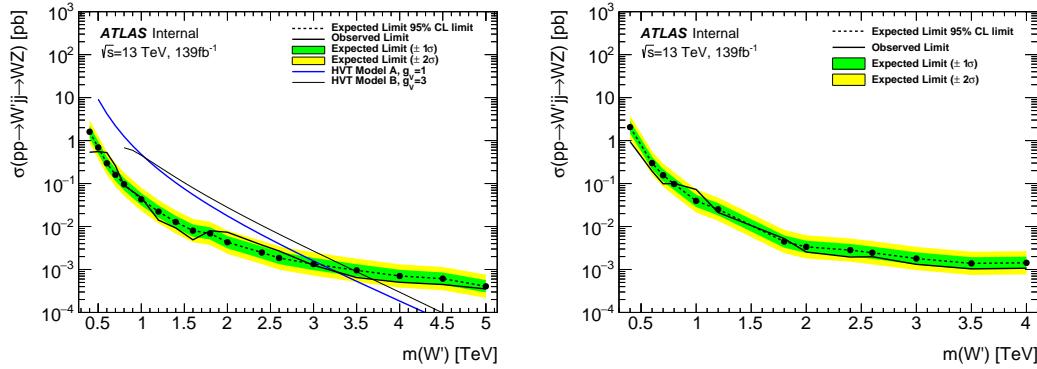

Figure 13.19: This figure shows theory, expected and observed limits for HVT Z' DY (left) and VBF (right) production.

1375

Quark and Gluon Tagging

1376

₁₃₇₇ **Chapter 14**

₁₃₇₈ **Prospects**

₁₃₇₉ For the resolved analysis, signal jets are quark enriched and background jets are
₁₃₈₀ gluon dominated. By classifying jets in the event as quark or gluon initiated, less
₁₃₈₁ background would contaminate the signal region. Figure 14.1 shows the PDGID
₁₃₈₂ for the truth parton matched to the jet (meaning the highest energy parton in
₁₃₈₃ the jet catchment area) in events passing the resolved signal region selections.
₁₃₈₄ PDGID = -1 corresponds to pileup jets, $0 < \text{PDGID} < 6$ correspond to quarks
₁₃₈₅ and $\text{PDGID} = 21$ corresponds to gluons. From this Figure, it is evident that a
₁₃₈₆ notable fraction of the background (all background events that passed the resolved
₁₃₈₇ SR are used) that contaminates the signal region contains gluon jets, especially
₁₃₈₈ for the sub-leading jet.

₁₃₈₉ As gluons jets have more constituents and therefore more tracks (n_{trk}), back-
₁₃₉₀ ground jets generally have more tracks than the signal jets. This is shown in
₁₃₉₁ Figure 14.2. Therefore, by cutting on the number of tracks in a jet, quark and
₁₃₉₂ gluon jets may be distinguished (i.e. jets with less than a given number of tracks
₁₃₉₃ are classified as a quark, otherwise the jet is classified as a gluon.) Moreover, as
₁₃₉₄ the momentum of the jet increases the number of tracks also increases logarith-
₁₃₉₅ mically [Cite nachman thesis Natasha], and improves tagging efficiency by about

1396 10% relative to a constant cut on the number of tracks. Therefore by applying a
1397 cut on the number of tracks that scales with the $\ln(p_T)$ is more powerful than a
1398 threshold cut on the number of tracks. Figures 14.3-14.6 show normalized heat
1399 maps of $\ln(p_T)$ vs the number of reconstructed tracks for the background and
1400 HVT Z' signals. This information is also shown in table ???. In these plots it is
1401 evident that the number of tracks in the background jets grows more quickly with
1402 $\ln(p_T)$ than for the signal jets. This is expected given that the signal is quark
1403 dominated and the background is gluon dominated.

1404 In Figure 14.7 is the ROC Curve for quark gluon tagging with cut on the
1405 number of tracks in a jet that depends on $\ln(p_T)$. The sum of the backgrounds
1406 in the signal region were used for this curve. Here the quark tagging efficiency is
1407 the ratio of quarks tagged as quarks to the total number of quarks in the signal
1408 region. The gluon rejection is calculated as the reciprocal of the gluon tagging
1409 efficiency. For example, choosing a 90% efficient working point with a rejection
1410 of 1.4 corresponds to a slope of 4 and intercept of -5. Tagging both jets in this
1411 analysis would yield an efficiency of $90\%^{n_{jets}}$. Focusing on the background in
1412 Figure 14.8, this cut helps minimize gluon contamination in the signal region.
1413 Also, from these heat maps it is obvious that the number of tracks in gluon jets
1414 grows more quickly than those in quark jets.

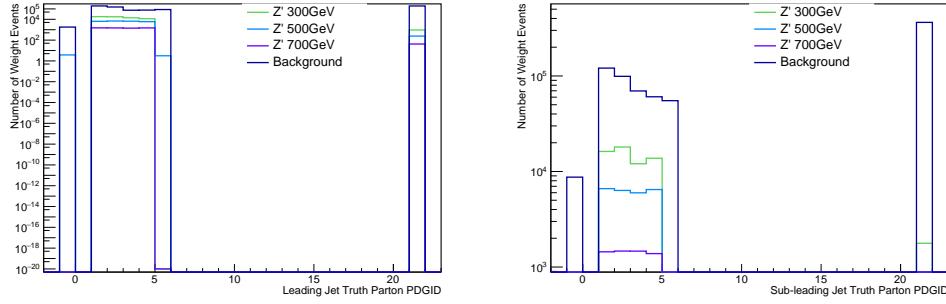

Figure 14.1: PDGID of the truth-level parton matched to the small-R jets passing the Resolved GGF WW Signal Region selections for the (a) Leading (b) Sub-Leading jets . These distributions are shown for 300, 500, and 700GeV Z' signals and the background (all simulated backgrounds that pass SR selections).

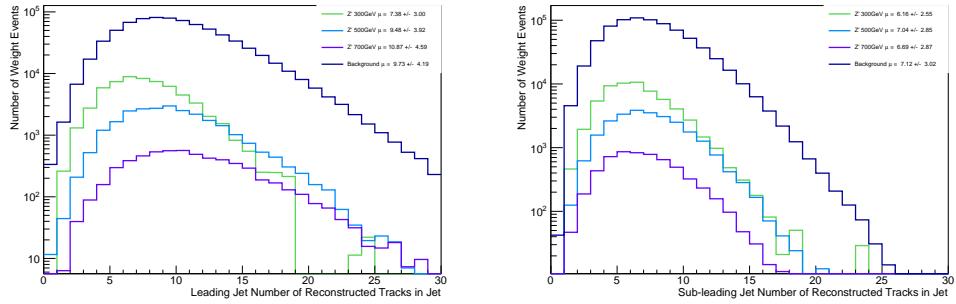

Figure 14.2: The number of tracks in small-R jets in events passing the Resolved GGF WW Signal Region selections for the (a) Leading (b) Sub-Leading jets. These distributions are shown for 300, 500, and 700GeV Z' signals and the background.

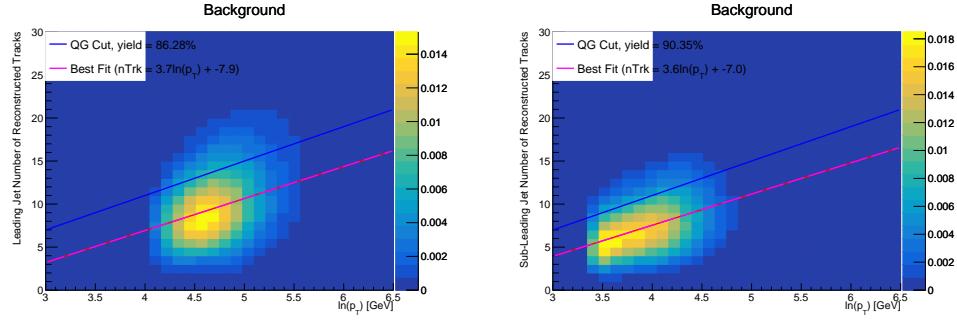

Figure 14.3: The number of tracks in background small-R jets in events passing the Resolved GGF WW Signal region selection vs. $\ln(p_T)$ for (a)Leading (b) Sub-Leading jets. The best fit line for the distribution is also shown, as well as the percentage of jets that pass a cut of number of tracks $< 4 \times \ln(p_T) - 5$. Note the number of total entries in these plots has been normalized to one.

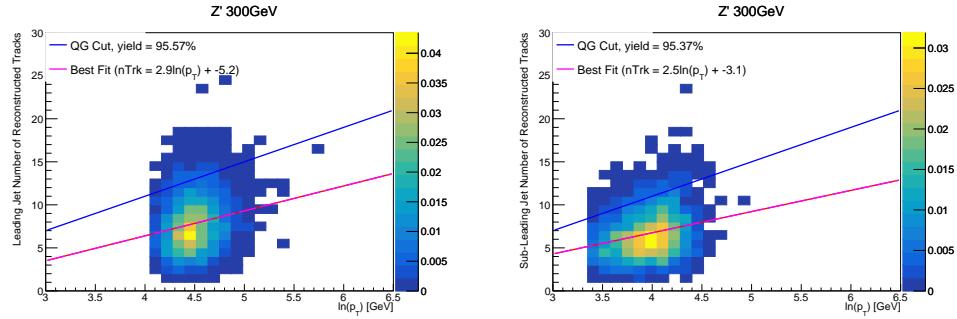

Figure 14.4: The number of tracks in small-R jets in 300GeV Z' events passing the Resolved GGF WW Signal region selection vs. $\ln(p_T)$ for (a)Leading (b) Sub-Leading jets. The best fit line for the distribution is also shown, as well as the percentage of jets that pass a cut of number of tracks $< 4 \times \ln(p_T) - 5$. Note the number of total entries in these plots has been normalized to one.

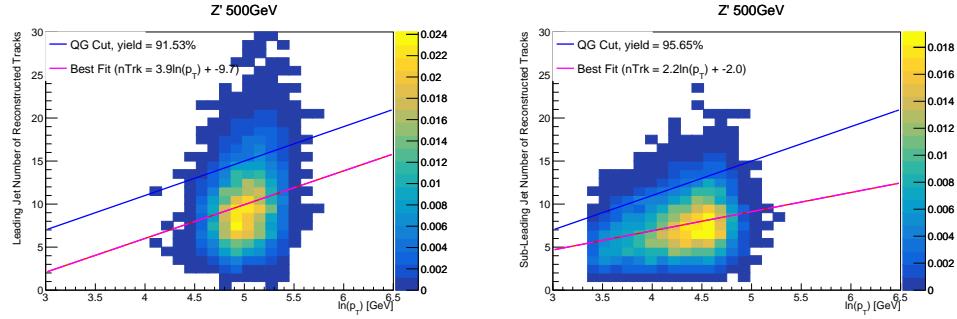

Figure 14.5: The number of tracks in small-R jets in 500GeV Z' events passing the Resolved GGF WW Signal region selection vs. $\ln(p_T)$ for (a)Leading (b) Sub-Leading jets. The best fit line for the distribution is also shown, as well as the percentage of jets that pass a cut of number of tracks $< 4 \times \ln(p_T) - 5$. Note the number of total entries in these plots has been normalized to one.

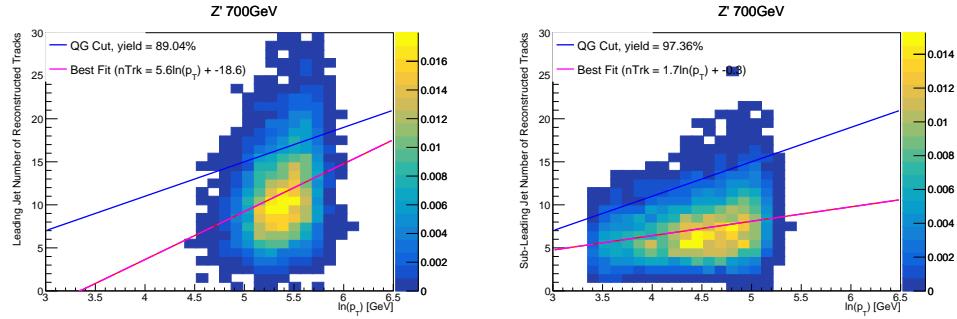

Figure 14.6: The number of tracks in small-R jets in 700GeV Z' events passing the Resolved GGF WW Signal region selection vs. $\ln(p_T)$ for (a)Leading (b) Sub-Leading jets. The best fit line for the distribution is also shown, as well as the percentage of jets that pass a cut of number of tracks $< 4 \times \ln(p_T) - 5$. Note the number of total entries in these plots has been normalized to one.

| Sample | Best Fit Slope | Best Fit Intercept | QG Tag Yield |
|------------------|----------------|--------------------|--------------|
| Backgrounds | 3.7 | -7.9 | 86% |
| HVT Z' 300 GeV | 2.9 | -5.2 | 95% |
| HVT Z' 500 GeV | 3.9 | -9.7 | 92% |

Table 14.1: This table shows the best fit slope and intercept for the 2-d distribution of number of tracks vs. jet $\ln(p_T)$ for the leading jet in the background and HVT Z' samples. The tagging efficiency is shown for the 90% working point in the last column. The background jets contain more gluons than the signal jets. Consequently, the best fit line for the background predicts larger values of the number of tracks in jets for the background than the considered signals.

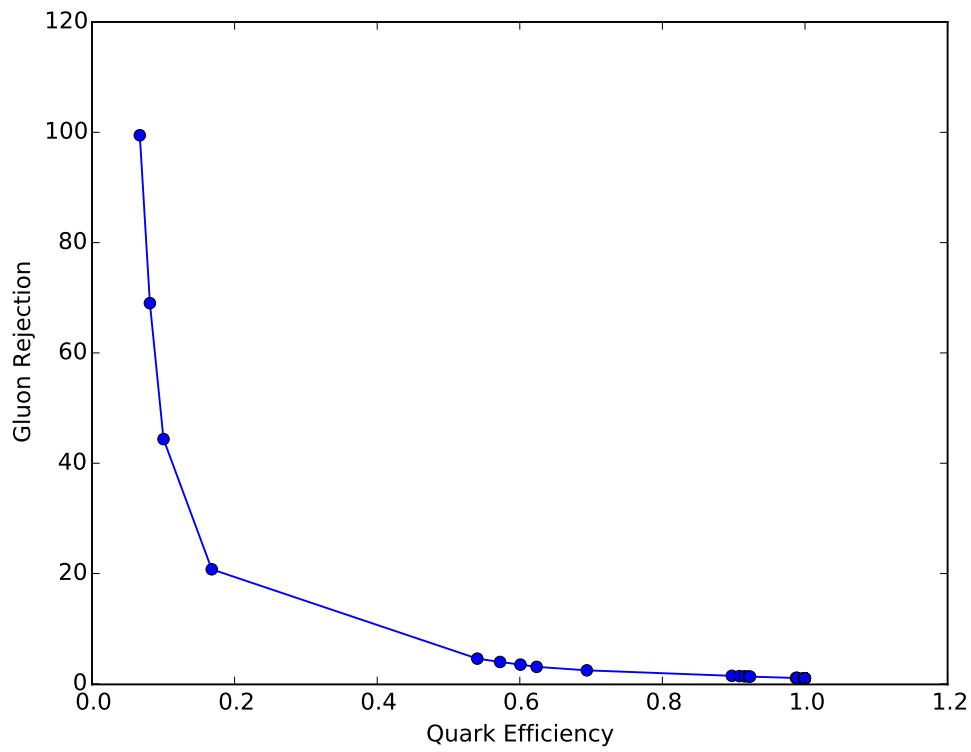

Figure 14.7: ROC Curve for Quark and Gluon Tagging with a cut on the number of tracks that depends on the $\ln(p_T)$.

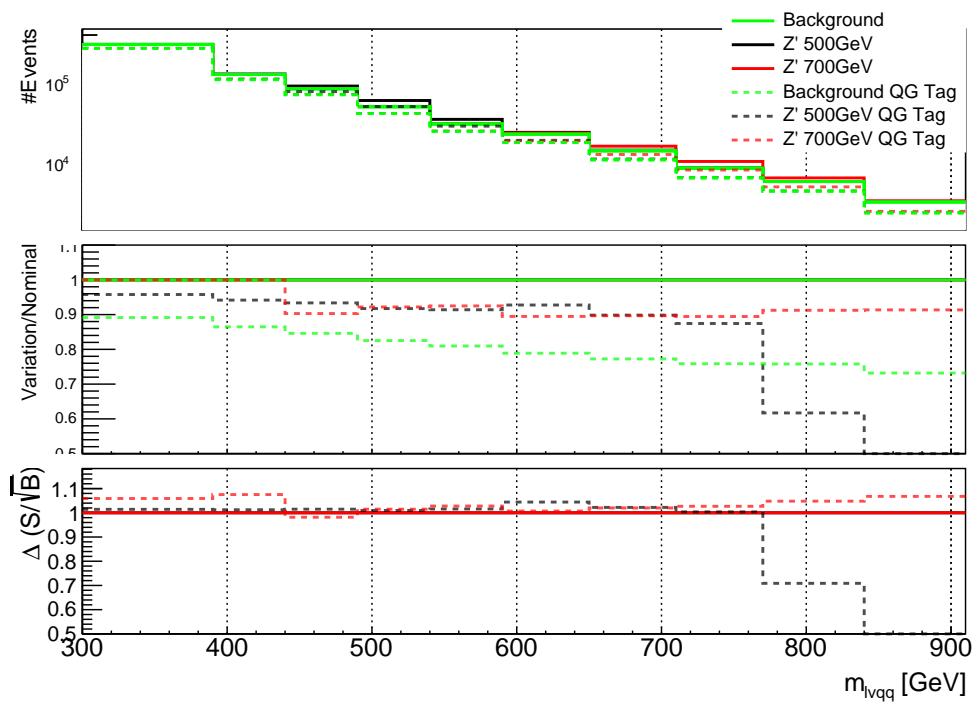

Figure 14.8: The top panel shows the distribution of m_{lvqq} with and without quark gluon tagging. The middle panel shows the ratio of the signals and backgrounds with and without quark gluon tagging. The bottom panel shows the change in S/\sqrt{B} with quark gluon tagging.

1415

Chapter 15

1416

n_{trk} Calibration

1417 The number of tracks in jets depends on modeling and experimental systemat-
1418 ics. Consequently, the efficiency of a quark-gluon tagger based on the number of
1419 tracks in jets would have associated uncertainties. In the context of the resonance
1420 search discussed, these uncertainties would be treated as systematics that impact
1421 the m_{WV} distributions that are used for discovery tests.

1422 Modeling uncertainties are obtained by assessing PDF and ME uncertainties
1423 on the number of charged particles in particle-level jets in dijet events. The
1424 number of charged particles as a function of jet p_T is calculated using an Iterative
1425 Bayesian (IB) technique [cite paper].

1426 This measurement ([9]) uses the ATLAS 2012 pp collision dataset, correspond-
1427 ing to $20.3/\text{fb}$ at center-of-mass energy $\sqrt{s} = 8\text{TeV}$. The number of charged con-
1428 stituents depends on fragmentation modeling and matrix elements, which do not
1429 depend on s . For this reason, it is safe to use these uncertainties for $\text{sqrt}(s)=13\text{TeV}$.
1430 Monte Carlo (MC) samples are used to determine the response matrix. The MC
1431 sample is a dijet sample generated with Pythia 8.175 using CT10 PDF and AU2
1432 tune. The anti- k_T algorithm is used to cluster jets with a radius parameter R
1433 = 0.4. Jets are required to have $|\eta| < 2.1$. Tracks in jets are required to have

1434 $p_T > 500\text{MeV}$, $|\eta| < 2.5$, track-fit $\chi^2 < 3.0$ and originate from the primary ver-
1435 tex. Matching tracks to jets is accomplished using ghost-association [cite]. In this
1436 technique, jets are re-clustered with the track collection augmented with "ghost"
1437 versions of tracks. These "ghosts" tracks have the same direction as their parent
1438 track, but infinitesimal track p_T . This insures meta-jet properties (e.g. η , p_T , etc)
1439 are unchanged. A track is matched to a jet if it's ghost version remains in the jet
1440 after re-clustering. Further details of the data, object, and event selection may be
1441 found in [cite 35].

1442 To select dijet topologies events are required to have at least two jets with
1443 $p_T > 50\text{GeV}$ that are relatively well-balanced ($p_T^{\text{lead}}/p_T^{\text{sub-lead}} < 1.5$).

1444 In the IB technique, the prior distribution and number of iterations are the
1445 inputs [cite Bayesian paper]. The IB response matrix connects number of charged
1446 particles to the number of tracks in jets determined using the simulated samples.
1447 This response matrix is used to unfold data to extract the n_c . Before applying
1448 the response matrix a fake factor is applied. This accounts for jets that pass
1449 detector level selections, but not particle level selections. Following this, the IB
1450 method iteratively applies the response matrix using the nominal Pythia 8.175
1451 sample as a prior. The number of IB iterations is chosen to minimize unfolding
1452 bias and statistical fluctuations. For this measurement four iterations was found
1453 to be optimal by minimizing the unfolding bias from pseudodata simulated with
1454 Herwig++ with a prior from Pythia 8 AU2. Finally, the inefficiency factor is
1455 applied to account for events passing particle level selection but not detector
1456 level, yielding the unfolded nCharged distribution.

1457 This process is prone to three main sources of bias: response matrix, correction
1458 factor, and unfolding procedure uncertainties. The response matrix is sensitive to
1459 experimental uncertainties impacting jet track reconstruction and calorimeter jet

1460 p_T . Correction factors are also sensitive to experimental uncertainties (e.g. JES)
 1461 as such uncertainties modify detector level acceptance. Sensitivity to particle
 1462 level acceptance is calculated by comparing Pythia and Herwig. Finally, the bias
 1463 from the IB prior choice is determined by reweighting the particle-level spectrum,
 1464 so the simulated detector level spectrum more closely matches the uncorrected
 1465 data. Unfolding this modified detector-level simulation and comparing it to the re-
 1466 weighted particle-level spectrum indicates bias from the prior distribution choice.

1467 A summary of all the systematic uncertainties associated with this unfolding
 1468 may be found in [ref paper]. Total uncertainties are < 7% for the number of
 1469 charged particles in jets. The unfolded distribution of the nCharged in jets from
 1470 data are further analyzed to extract the quark and gluon nCharged distributions.
 1471 In dijet events, the jet with a larger η is more energetic and therefore more likely
 1472 to be a quark. This is due to the quarks in protons generally having a larger
 1473 fraction of the total momentum of the proton constituents. The more central jet
 1474 is more likely to be a gluon-initiated jet. This correlation between jet η and flavor
 1475 may then be used to extract nCharged in p_T bins using:

$$\langle n_c^f \rangle = f_q^f \langle n_c^q \rangle + f_g^f \langle n_c^g \rangle \quad (15.1)$$

1476

$$\langle n_c^c \rangle = f_q^c \langle n_c^q \rangle + f_g^c \langle n_c^g \rangle \quad (15.2)$$

1477 In this equation the f and c subscripts denote the more forward and central
 1478 jets, respectively. The q and g subscripts denote quark and gluon. The fraction
 1479 of more forward jets that are say gluons is denoted by f_g^f . The other relevant jet
 1480 fractions are denoted with the same naming scheme. Finally, $\langle n_c \rangle$ is the average
 1481 number of charged particles in a jet in a given p_T bin. To show that Eq. (??) may
 1482 be used to extract quark and gluon n_c distributions the extracted distributions
 1483 are compared to n_c distributions determined using the jet flavor in simulation.

1484 Figure [add figure natasha] shows that the extracted and true distributions differ
1485 by < 1% over the p_T range probed for this study. Moreover, this implies that n_c
1486 depends only on the flavor of the initiating parton and jet p_T .

1487 These extracted distributions are prone to PDF and ME biases. The bias from
1488 the choice of the CT10 PDF for the Pythia sample is accounted for by comparing
1489 quark/gluon fractions for the nominal CT10 sample with its eigenvector variations.
1490 Comparing the quark/gluon fractions from Pythia 8 and Herwig++ quantify the
1491 uncertainty from the ME calculation. These uncertainties are added in quadra-
1492 ture with the unfolding uncertainty to give the total modelling uncertainty on
1493 the extracted n_c distribution. This is shown in Figure 16.2.

1494 To apply these uncertainties in n_c distributions in data, per-jet event weights
1495 are associated with each uncertainty according to:

$$w_i(n_c) = \frac{P(n_c | n_c > \pm \sigma_{n_c}^i)}{P(n_c | n_c >)} \quad (15.3)$$

1496 In Eq. (??), i denotes the uncertainty considered, P is the Poisson probability,
1497 and $\sigma_{n_c}^i$ represents the average impact of the uncertainty on n_c .

1498 The previous uncertainties described accounted for modeling uncertainty as-
1499 sociated with the number of charged particles in a jet. However, n_c is not a
1500 measurable quantity. Instead the number of tracks in a jet is measured, which is
1501 a proxy for n_c . Therefore the uncertainties associated with the measurement of
1502 nTracks must also be considered ([11]). These uncertainties were calculated using
1503 a Pythia 8 dijet sample with NNPDF 23 and Run 2 data. Track reconstruction
1504 efficiency and fake rates are the dominant sources of nTrack uncertainties.

1505 The track reconstruction efficiency is affected by the uncertainty of the de-
1506 scription of the ID material in simulation and the modeling of charged-particle
1507 interactions with this material. These uncertainties are accounted for by varying

1508 the ID material by 5-25% (dependent on the region of the detector considered).
1509 The difference in the tracking efficiency between the nominal and varied simula-
1510 tion give the uncertainty on the track reconstruction efficiency. Another important
1511 source of track reconstruction inefficiency arises in the core of jets. The high den-
1512 sity of tracks in the jet cores can cause ID clusters to merge. The fraction of lost
1513 tracks due to merging is given by the fraction of tracks that have a charge of two
1514 minimum ionizing particles. This quantity is compared between data and simu-
1515 lation resulting in an uncertainty of 0.4% on tracks with $\Delta R < 0.1$. Combining
1516 these effects gives a total uncertainty as a function of p_T and η that is generally
1517 $< 2\%$ [references figure 44 from [11]].

1518 Fake tracks are the other dominant source of nTrk uncertainty. Fake tracks
1519 are tracks that cannot be associated to a single particle. Often these tracks are a
1520 result of random combinations of hits from charged particles that overlap in space.
1521 In dense environments, such as the core of jets or high-pileup environments, fake
1522 tracks are more likely. Fake tracks are estimated with a 'control region method'
1523 which is briefly summarized here [[10]]. By applying a series of track selections
1524 to enrich the fraction of fake tracks (e.g. $|d_0| > 0.1$, track $\chi^2 > 1.4$, etc) in
1525 simulation, templates for fake track parameters are calculated. These templates
1526 are then fit to data to determine the fraction of fake tracks. On average the fake
1527 rate is found to be 30% (independent of p_T and η).

1528 To assess the impact of these two detector level uncertainties, tracks are ran-
1529 domly dropped according to the rates described above. Reconstruction and fake
1530 uncertainties both lower the number of tracks, hence these uncertainties are one-
1531 sided. By dropping tracks in this way a varied nTrk distribution is calculated for
1532 both uncertainties. The associated per-jet event weights are then calculated in
1533 the same way as the modeling weights as:

$$w_i(n_c) = \frac{P(n_{trk} | < n_{trk} > \pm \sigma_{n_{trk}}^i)}{P(n_{trk} | < n_{trk} >)} \quad (15.4)$$

1534 Adding the modeling and detector level uncertainties in quadrature gives the
 1535 overall nTrack uncertainty. The effects of the individual uncertainties on the nTrk
 1536 distributions can be seen in Fig 16.4. Fig 16.3 shows the m_{lvqq} and nTrk distri-
 1537 butions for the W and Top control regions before likelihood fitting. In these plots
 1538 the nTrk uncertainties improve agreement between data and MC. The remaining
 1539 differences are likely covered by likelihood fitting and improving the analysis itself.

1540 **Chapter 16**

1541 **Application**

1542 Using the 90% WP of the n_{trk} tagger improves S/\sqrt{B} is $\sim 3\%$ as shown in
1543 Figure 14.8. Although, n_{trk} is the single most powerful discriminating variable
1544 for quark and gluon jets, the addition of other jet variables would improve the
1545 classification efficiency. Figure 16.1 shows the possible improvement of 10%
1546 in jet classification using the truth label of the jets to classify jets. This type of
1547 improvement is possible by using variables such as jet width, and energy correlata-
1548 tors. Figure [add BDT figure/use 1612.01551.pdf] shows for a 90% quark tagging
1549 efficiency for a 100 GeV jet, a BDT improve the gluon rejection by 0.4. Once this
1550 tagger is calibrated it would improve the analysis sensitivity of this channel.

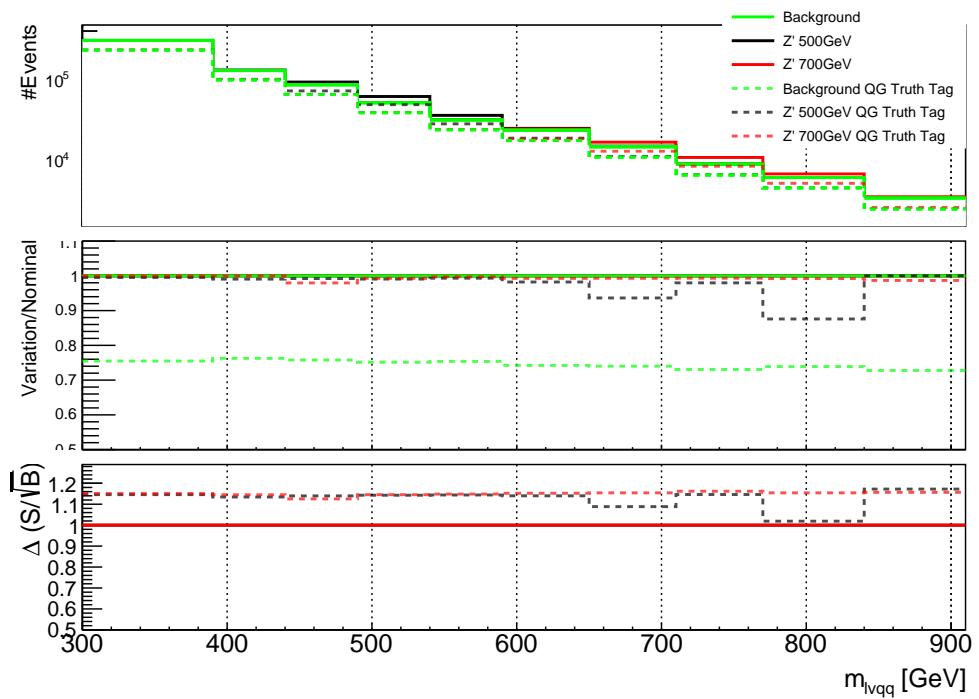

Figure 16.1: The top panel shows the distribution of m_{lvqq} with and without requiring jets to be true quarks. The middle panel shows the ratio of the signals and backgrounds with and without requiring jets to be true quarks. The bottom panel shows the change in S/\sqrt{B} when requiring jets to be true quarks..

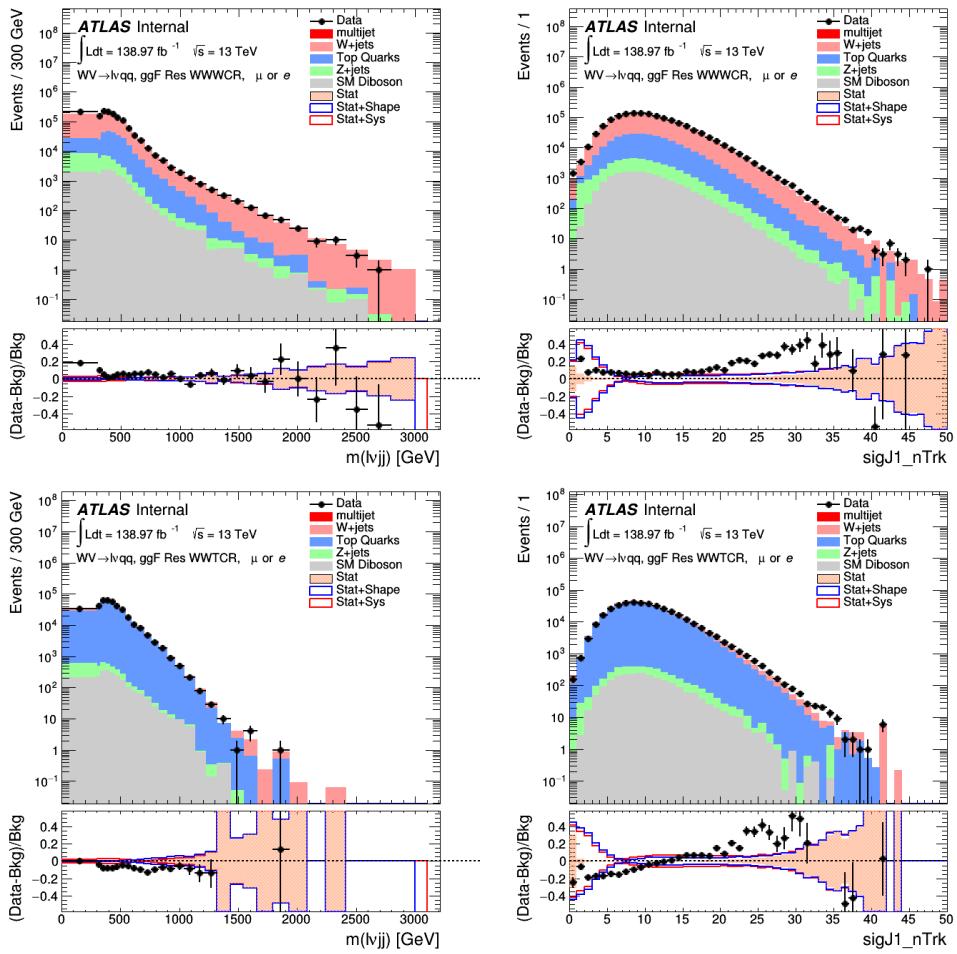

Figure 16.3: PDGID of the truth-level parton matched to the small-R jets passing the Resolved GGF WW Signal Region selections for the (a) Leading (b) Sub-Leading jets . These distributions are shown for 300, 500, and 700GeV Z' signals and the background.

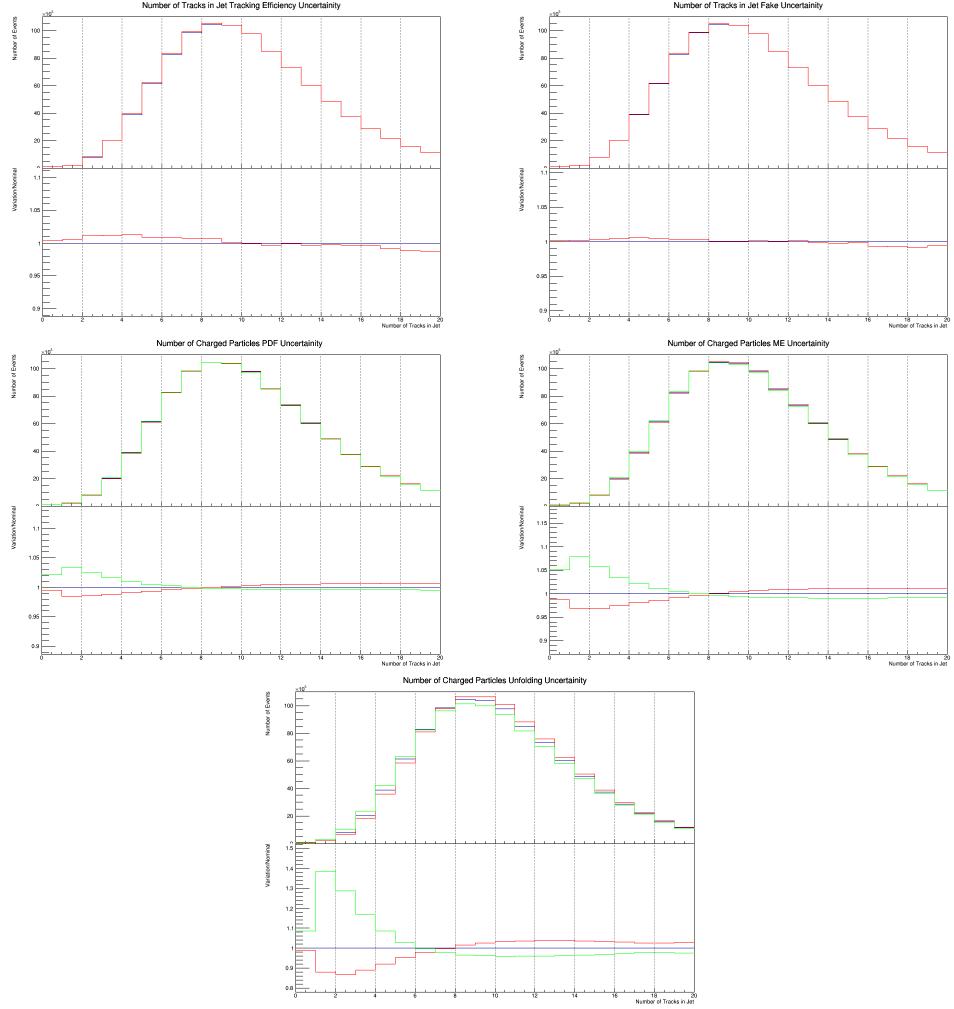

Figure 16.4: These figures show the impact of the uncertainties on the number of tracks in the leading jet in the sum of the background sample in the Resolved GGF WW SR (a) tracking efficiency (b) fake (c) PDF (d) ME (e) unfolding uncertainties.

Part VI

1551

Conclusion

1552

1553 **Chapter 17**

1554 **Conclusions**

1555 A search for WW and WZ diboson resonance production in $\ell\nu qq$ final states
1556 was performed using 139fb^{-1} of pp collision data collected at a center-of-mass
1557 energy of $\sqrt{s} = 13\text{TeV}$ by that ATLAS detector at the LHC between 2015 and
1558 2018. No excess of events above the background-only expectation was observed.
1559 The largest local excess is approximately 2.7σ , which is not significant. Limits
1560 on the production cross section are obtained for the HVT W' and Z' and RS
1561 Gravitons. Signal masses below 3.4 (3.7) TeV are excluded for HVT W' Model
1562 A(B). Signal masses below 3.3 (3.7) TeV are excluded for HVT Z' Model A(B).
1563 Randall Sundrum Gravitons are excluded for masses below 1.6 TeV. Going forward,
1564 improving the classification of jets in events would improve analysis sensitivity.
1565 To distinguish quark from gluon jets a jet tagger based on the number of tracks in
1566 jets is studied in the context of this search. Finally, the calibration of the number
1567 of tracks in jets is discussed.
