Abstract

Search for WW and WZ resonance production in $\ell\nu qq$ final states in pp collisions at $\sqrt{s} = 13$ TeV with the ATLAS detector

by

Natasha Woods

This thesis reviews a search for WW and WZ resonance production using data from pp collisions at $\sqrt{s} = 13$ TeV using the ATLAS detector, corresponding to an integrated luminosity of 139 fb^{-1} . Diboson resonances are predicted in a number of Standard Model (SM) extensions, such as Extended Gauge Models, Extra dimensions, and technicolor models. This search looks for resonances where one W boson decays leptonically and the other W or Z boson decays hadronically. This search is sensitive to diboson resonance production via vector-boson fusion as well as quark-antiquark annihilation and gluon-gluon fusion mechanisms. No significant excess of events is observed with respect to the Standard Model backgrounds. As the dominant backgrounds in this search contain gluons, classifying jets as quark or gluon initiated would make this analysis more sensitive to new physics. Towards this end, this thesis considers the prospects for adding a quark gluon tagger based on the number of tracks in jets and reviews the calibration of the number of tracks in jets.

A loving dedication.

Part I

³

Theoretical Motivation

⁴ **Chapter 1**

⁵ **The Standard Model of Particle
6 Physics**

⁷ **1.1 Introduction**

⁸ By determining the dynamics of the most elementary degrees of freedom, par-
⁹ ticle physics hopes to uncover the fundamental laws of the universe. The definition
¹⁰ of elementary has evolved through time and currently refers to matter and force
¹¹ mediating particles: fermions and bosons, respectively. The Standard Model of
¹² Particle Physics (SM) describes the quantum behavior of three of the four funda-
¹³ mental forces: weak, strong, and electromagnetic, via boson and fermion interac-
¹⁴ tions. Gravity is not included in the SM and still under investigation.

¹⁵ **1.2 Quantum Field Theory**

¹⁶ In the SM, forces (and particles) are represented as fields. In this context,
¹⁷ fields are mathematical objects that define a tensor (e.g. scalar, vector, etc) at
¹⁸ every point on a manifold, here the manifold is space-time. These fields obey laws

¹⁹ dictated by Quantum Field Theory (QFT). Particles arise naturally in QFT as
²⁰ quantized field excitations localized in spacetime.

²¹ According to Noether's theorem, symmetries of a field give rise to conserved
²² quantities (e.g. time-translation invariance leads to energy conservation). Often
²³ in the history of physics, a conserved quantity of a field is found and then the
²⁴ underlying symmetry of the field is inferred. Gauge symmetries are symmetries
²⁵ among the internal degrees of freedom of the field (components of the tensor),
²⁶ which give rise to quantities associated with fields. By specifying the symmetries
²⁷ of a system the dynamics and conserved quantities of the system may be succinctly
²⁸ defined.

²⁹ 1.3 $U(1)_{EM}$ Local Gauge Invariance

³⁰ The Lagrangian of Quantum Electrodynamics (QED) describes the electro-
³¹ magnetic force. QED may be derived by requiring local $U(1)_{EM}$ gauge invariance
³² of the free dirac fermion Lagrangian, ψ :

$$\mathcal{L} = i\bar{\psi}\gamma^\mu\partial_\mu\psi - m\bar{\psi}\psi \quad (1.1)$$

³³ This symmetry may be represented as a complex number with unit modulus,
³⁴ $e^{i\theta}$. $U(1)$ gauge invariance requires this gauge transformation of ψ will leave the
³⁵ Lagrangian unchanged.

$$\psi(x) \rightarrow \psi'(x) = e^{i\theta(x)}\psi(x) \quad (1.2)$$

³⁶ NB: This transformation is a local gauge transformation as θ depends on the
³⁷ spacetime coordinate.

³⁸ By requiring this symmetry of the free Dirac fermion Lagrangian:

$$\mathcal{L} = i\bar{\psi}\gamma^\mu\partial_\mu\psi - m\bar{\psi}\psi \quad (1.3)$$

³⁹ The mass term is unaffected, but the kinetic term is modified due to $\theta(x)$.

$$\mathcal{L} \rightarrow \mathcal{L}' = i\bar{\psi}e^{-i\theta(x)}\gamma^\mu\partial_\mu\psi e^{i\theta(x)} - m\bar{\psi}e^{-i\theta(x)}\psi e^{i\theta(x)} \quad (1.4)$$

⁴⁰

$$= i\bar{\psi}\gamma^\mu(\partial_\mu\psi + i\psi\partial_\mu\theta) - m\bar{\psi}\psi \quad (1.5)$$

⁴¹ The $\partial_\mu\theta$ terms breaks the gauge invariance of the Lagrangian. By introducing a
⁴² new field, A_μ we can recover the gauge invariance of the derivative. Now redefining
⁴³ the derivative as the covariant derivative:

$$D_\mu\psi \equiv (\partial_\mu - iqA_\mu)\psi \quad (1.6)$$

⁴⁴ And letting A_μ transform under $U(1)$ as:

$$A_\mu \rightarrow A_\mu + \delta A_\mu \quad (1.7)$$

⁴⁵ The transformed covariant derivative becomes:

$$D_\mu\psi \rightarrow D_\mu\psi' = (\partial_\mu - iqA_\mu)\psi' \quad (1.8)$$

⁴⁶

$$= (\partial_\mu - iq(A_\mu + \delta A_\mu))\psi e^{i\theta} \quad (1.9)$$

⁴⁷

$$= e^{i\theta}D_\mu + ie^{i\theta}\psi(\partial_\mu\theta - q\delta A_\mu) \quad (1.10)$$

⁴⁸ The covariant derivative can be made gauage invariant by setting the last term
⁴⁹ to zero.

$$\delta A_\mu = \frac{1}{q} \partial_\mu \theta \quad (1.11)$$

50 So now A_μ transforms as:

$$A_\mu \rightarrow A_\mu + \frac{1}{q} \partial_\mu \theta \quad (1.12)$$

51 Finally, replacing the derivative with the covariant derivative the Dirac La-
52 grangian we have:

$$\mathcal{L} = i\bar{\psi}\gamma^\mu D_\mu \psi - m\bar{\psi}\psi - \frac{1}{4}F_{\mu\nu}F^{\mu\nu} \quad (1.13)$$

53

$$= \mathcal{L}_{QED} \quad (1.14)$$

54 Here $F_{\mu\nu} \equiv \partial_\mu A_\nu - \partial_\nu A_\mu$. This last term in the Lagrangian is the kinetic
55 energy of the gauge boson field.

56 So we have derived the QED Lagrangian. By requiring the free Dirac La-
57 grangian to be invariant under U(1) transformations we have generated a new
58 gauge boson field, A_μ , which describes the photon. As expected the photon inter-
59 acts with fermions.

60 Stepping back, a global U(1) gauge symmetry of the free Dirac Lagrangian
61 implies we cannot measure the absolute phase of a charged particle. A local U(1)
62 gauge symmetry changes the phase of fields differently across space time. For this
63 type of transformation to leave the Lagrangian invariant, we had to introduce an
64 additional field, A_μ , which "communicates" these phase changes across space-time.
65 In less formal language this effectively means: if the field at one location changes,
66 this change is conferred to other particles via A_μ .

67 1.4 Yang-Mills Gauge Theories

68 Requiring $U(1)_{EM}$ gauge invariance of the free Dirac Lagrangian gave us QED.

69 Requiring different gauge symmetries we can derive the structure of other inter-
70 actions. Any gauge symmetry may be written as:

$$\psi_i \rightarrow \exp(i\theta^a T_{ij}^a) \psi_j \quad (1.15)$$

71 Here θ is a dimensionless real parameter and T is the generator of the gauge
72 symmetry group. With this the covariant derivative can be written as:

$$D_\mu \psi_i \equiv \partial_\mu \psi_i + ig A_\mu^a T_{ij}^a \psi_j \quad (1.16)$$

73 Then the gauge field must transform as:

$$A_\mu^a \rightarrow A_\mu^a - \frac{1}{g} \partial_\mu \theta^a - f^{abc} \theta^b A_\mu^c \quad (1.17)$$

74 Here f is the structure constant of the gauge group. The field strength tensor
75 is given by:

$$F_{\mu\nu}^a \equiv \partial_\mu A_\nu^a - \partial_\nu A_\mu^a - g f^{abc} A_\mu^b A_\nu^c \quad (1.18)$$

76

$$F_{\mu\nu}^a \rightarrow F_{\mu\nu}^a - f^{abc} \theta^b F_{\mu\nu}^c \quad (1.19)$$

77 This gives the Yang-Mills Lagrangian:

$$\mathcal{L}_{YM} = -\frac{1}{4} F_{\mu\nu}^a F_{\mu\nu}^a + i \bar{\psi}_i \gamma^\mu D_\mu \psi_i + m \bar{\psi}_i \psi_i \quad (1.20)$$

78 1.5 Particles in the Standard Model

79 The SM consists of fermions (half-integer spin matter constituents) and bosons
80 (integer spin force mediators). Fermions are spinor representations of the Poincare
81 group and can be further separated into leptons and quarks. Bosons are the result
82 of requiring a particular symmetry among the spinor fields:

$$SU(3)_C \times SU(2)_L \times U(1)_Y \quad (1.21)$$

83 $SU(3)_C$ is the symmetry group of the strong force and generates eight gluon
84 fields, G_μ . $SU(2)_L$ is the symmetry group of the Electroweak force and generates
85 three electroweak boson fields, and $U(1)_Y$ generates the photon field, where Y is
86 the weak-hypercharge:

$$Y = 2(Q - T_3) \quad (1.22)$$

87 Q is the electromagnetic charge, and T_3 is the z-component of the weak isospin.
88 Weak isospin is the charge associated with the $SU(2)_L$ symmetry. The correspond-
89 ing covariant derivative is then:

$$D_\mu \phi \equiv (\partial_\mu + ig_1 B_\mu Y_{L/R} + [ig_2 W_\mu^\alpha T^\alpha]_L + [ig_3 G_\mu^\alpha \tau^\alpha]_C) \psi \quad (1.23)$$

90 It is important to note that the gauge symmetry of the SM yields a particular
91 structure of the fermion representations. So for a given fermion to interact with
92 a given gauge field it must have a non-zero corresponding Noether charge for
93 that gauge symmetry. If the corresponding Noether charge is zero, that fermion
94 transforms as a singlet and does not participate in that gauge interaction.

95 Fermions are divided into quarks and leptons based on their transformations
96 under $SU(3)_C$. Quarks transform as color triplets. Leptons transform as color

singlets and consequently do not interact with gluons. Fermions may be further
 classified by their $SU(2)_L$ interactions. Only the left-chiral part of fermions (denoted by L here) transform as $SU(2)_L$ doublets, the right-chiral part forms singlets under this gauge. Lastly, all these groups of particles come in three generations, each a heavier copy of the previous, but with differing flavor quantum numbers.
 This is summarized in Table 1.1 and shown in Figures 1.1 and 1.2.

SM Fermion Gauge Group	First Generation	Second Generation	Third Generation	$(SU(3)_C, SU(2)_L, U(1)_Y)$ Representations
Left-handed quarks	$\begin{pmatrix} u_L^r & u_L^g & u_L^b \\ d_L^r & d_L^g & d_L^b \end{pmatrix}$	$\begin{pmatrix} c_L^r & c_L^g & c_L^b \\ s_L^r & s_L^g & s_L^b \end{pmatrix}$	$\begin{pmatrix} t_L^r & t_L^g & t_L^b \\ b_L^r & b_L^g & b_L^b \end{pmatrix}$	$(3, 2, \frac{1}{6})$
Right-handed quarks	(u_R^r, u_R^g, u_R^b) (d_R^r, d_R^g, d_R^b)	(c_R^r, c_R^g, c_R^b) (s_R^r, s_R^g, s_R^b)	(t_R^r, t_R^g, t_R^b) (b_R^r, b_R^g, b_R^b)	$(3, 1, \frac{2}{3})$ $(3, 1, -\frac{1}{3})$
Left-handed leptons	$\begin{pmatrix} \nu_e^L \\ e_L \end{pmatrix}$	$\begin{pmatrix} \mu_e^L \\ \mu_L \end{pmatrix}$	$\begin{pmatrix} \tau_e^L \\ \tau_L \end{pmatrix}$	$(1, 2, -\frac{1}{2})$
Right-handed leptons	e_R	μ_R	τ_R	$(1, 1, -1)$

Table 1.1: Representations of the SM fermions under $SU(3)_C \times SU(2)_L \times U(1)_Y$ gauge symmetry group. $SU(2)_L$ gauge transformations allow one to go between rows and $SU(3)_C$ transformations allow one to go between columns in these fermion representations. [REWORD]

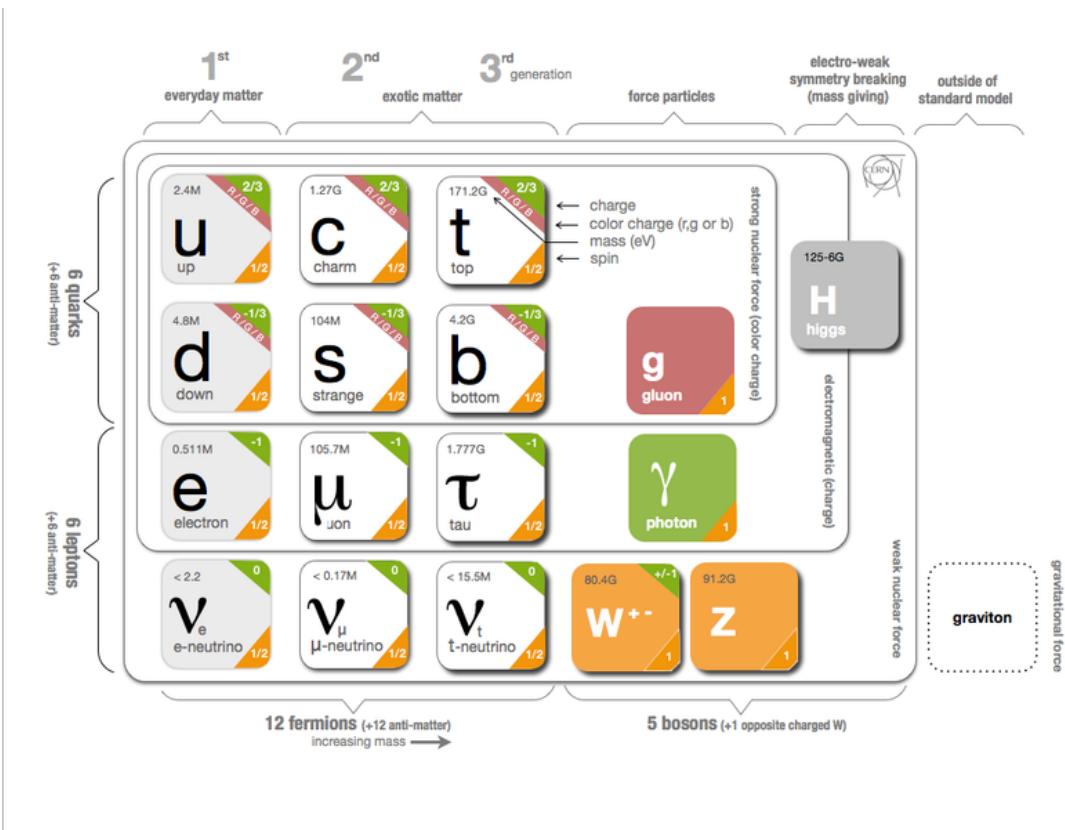

Figure 1.1: The particles of the Standard Model.

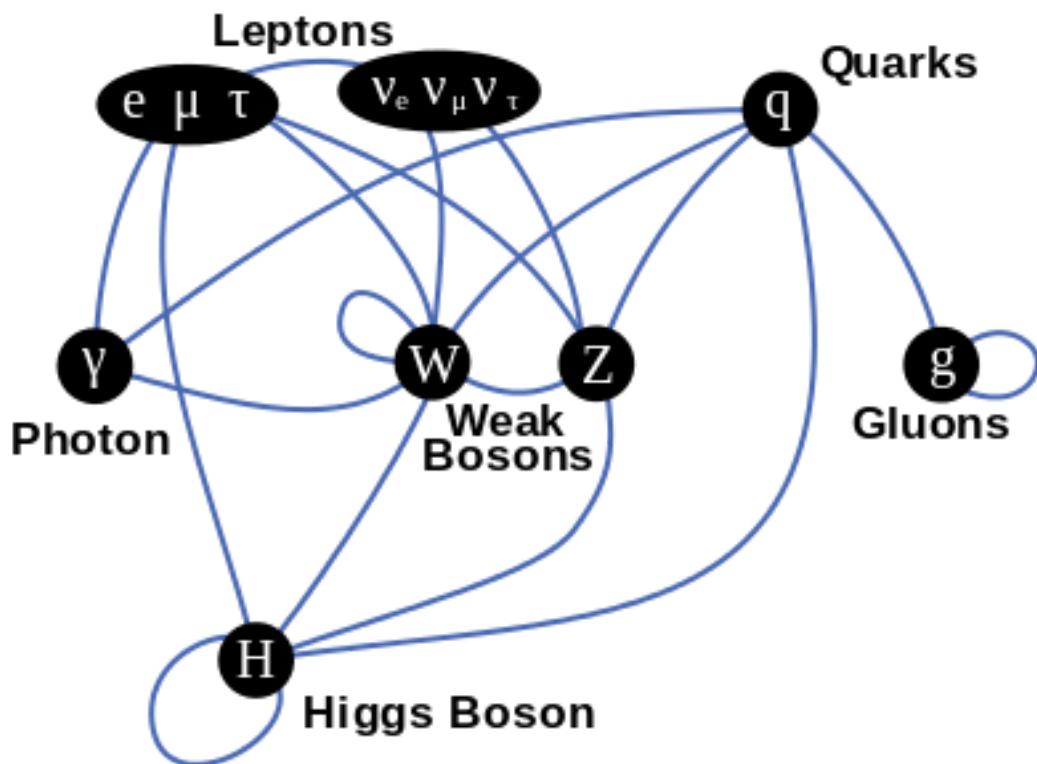

Figure 1.2: Summary of how Standard Model particles interact with other Standard Model particles.

¹⁰³ Now we can understand the SM Lagrangian density as a Yang-Mills theory
¹⁰⁴ with the gauge group: $SU(3)_C \times SU(2)_L \times U(1)_Y$ with an additional $SU(2)$ complex
¹⁰⁵ scalar Higgs field doublet that will be discussed later.

$$\begin{aligned} \mathcal{L}_{SM} = & \underbrace{-\frac{1}{4}B_{\mu\nu}B^{\mu\nu} - \frac{1}{4}W_{\mu\nu}^a W^{a\mu\nu} - \frac{1}{4}G_{\mu\nu}^\alpha G^{\alpha\mu\nu}}_{\text{Kinetic Energies and Self-Interactions of Gauge Bosons}} \\ & + \underbrace{\bar{L}_i \gamma^\mu (i\partial_\mu - \frac{1}{2}g_1 Y_{iL} B_\mu - \frac{1}{2}g_2 \sigma^a W_\mu^a) L_i}_{\text{Kinetic Energies and EW Interactions of Left-handed Fermions}} \\ & + \underbrace{\bar{R}_i \gamma^\mu (i\partial_\mu - \frac{1}{2}g_1 Y_{iR} B_\mu) R_i}_{\text{Kinetic Energies and EW Interactions of Right-Handed Fermions}} \\ & + \underbrace{\frac{ig_3}{2} \bar{Q}_j \gamma^\mu \lambda^\alpha G_\mu^\alpha Q_j}_{\text{Strong Interactions between Quarks and Gluons}} \\ & + \underbrace{\frac{1}{2} |(i\partial_\mu - \frac{1}{2}g_1 B_\mu - \frac{1}{2}g_2 \sigma^a W_\mu^a)\Phi|^2 - V(\Phi)}_{\text{Electroweak Boson Masses and Higgs Couplings}} \\ & - (\underbrace{y_{kl}^d \bar{L}_k \Phi R_l + y_{kl}^u \bar{R}_k \tilde{\Phi} L_l + h.c.}_{\text{Fermion Mass terms and Higgs Couplings}}) \end{aligned}$$

¹⁰⁶ Here several abstract spaces are being spanned:

- ¹⁰⁷ – a spans the three $SU(2)_L$ gauge fields with generators expanded in Pauli
¹⁰⁸ matrices, $T^\alpha = \frac{1}{2}\sigma^\alpha$
- ¹⁰⁹ – α spans the eight $SU(3)_C$ gauge fields, with generators expanded in Gell-
¹¹⁰ Mann matrices, $\tau^\alpha = \frac{1}{2}\lambda^\alpha$
- ¹¹¹ – L/R represent left and right projections of Dirac fermion fields. The Strong
¹¹² interaction is not chiral, so $Q = L+R$

113 – μ and ν are four-vector indices

114 – i, j, k are summed over the three generations of SM particles.

115 1.6 Higgs Mechanism

116 The SM Lagrangian without the addition of a Higgs field does not allow for
117 gauge boson and fermion mass terms: $\frac{1}{2}m_A^2 A_\mu A_\mu$ and $m(\bar{\psi}\psi)$, as these terms are
118 not gauge invariant. By introducing the Higgs field, mass terms for these particles
119 may be included in a gauge invariant way. This field is a complex doublet with a
120 potential $V(\Phi)$:

$$\Psi = \begin{pmatrix} \Phi^\dagger \\ \Phi^0 \end{pmatrix} \quad (1.24)$$

121 $V(\Phi) = \mu^2 \Phi^\dagger \Phi + \lambda |\Phi^\dagger \Phi|^2 \quad (1.25)$

122 The minima of this field occurs for $|\Phi| = \sqrt{\frac{\mu^2}{2\lambda}} \equiv \frac{v}{2}$. This yields degenerate
123 minima, this symmetry is broken by choosing a specific minima (a.k.a. sponta-
124 neous symmetry breaking). By convention $\Phi_{min} = \frac{1}{\sqrt{2}} \begin{pmatrix} 0 \\ v \end{pmatrix}$ is chosen. This means
125 the ground state of the Higgs field (Higgs vacuum) is non-zero, $\sqrt{\frac{-\mu^2}{\lambda}}$. The Higgs
126 Field may now be expanded around this new ground state:

$$\Phi(x) = \frac{1}{\sqrt{2}} \begin{pmatrix} 0 \\ v + h(x) \end{pmatrix} \quad (1.26)$$

127 This non-zero Higgs vacuum now generates mass terms for the gauge bosons
128 from the following term in the Lagrangian:

$$|(-\frac{1}{2}g_1B_\mu - \frac{1}{2}g_2\sigma^aW_\mu^a)\Phi|^2 = \frac{1}{2}m_W^2W_\mu^+W^{-\mu} + \frac{1}{2}m_Z^2Z_\mu Z^\mu \quad (1.27)$$

129 where:

$$W_\mu^\pm \equiv \frac{1}{\sqrt{2}}(W_\mu^1 \mp iW_\mu^2) \quad (1.28)$$

$$\begin{aligned} \text{130} \quad Z_\mu &\equiv \frac{1}{\sqrt{g_1^2 + g_2^2}}(g_2W_\mu^2 - g_1B_\mu) \end{aligned} \quad (1.29)$$

$$\begin{aligned} \text{131} \quad m_W &= \frac{vg_2}{\sqrt{2}} \end{aligned} \quad (1.30)$$

$$\begin{aligned} \text{132} \quad m_Z &= \frac{v}{\sqrt{2}}\sqrt{g_1^2 + g_2^2} \end{aligned} \quad (1.31)$$

133 The Higgs field also generates a mass term for the Higgs boson and self-
134 interactions for the Higgs boson.

135 1.7 Electroweak Theory

136 $SU(2)_L$ generates W^\pm, W^0 gauge bosons, which would be massless if $SU(2)_L$
137 was a perfect symmetry. These bosons are massive as this symmetry is broken.

138 The mass eigenstates, Z and γ given by:

$$\begin{pmatrix} Z_\mu \\ A_\mu \end{pmatrix} = \begin{pmatrix} \cos\theta_W & -\sin\theta_W \\ \sin\theta_W & \cos\theta_W \end{pmatrix} \begin{pmatrix} W_\mu^3 \\ B_\mu \end{pmatrix} \quad (1.32)$$

139 Here θ_W is the Weinberg angle given by:

$$\cos\theta_W = \frac{g_2}{\sqrt{g_1^2 + g_2^2}} = \frac{m_W}{m_Z} \quad (1.33)$$

¹⁴⁰ 1.8 Quantum ChromoDynamics

¹⁴¹ As mentioned earlier the Strong Force, which binds the proton together, is
¹⁴² mediated by gluons. Quantum Chromodynamics is the QFT which describes the
¹⁴³ interactions of quarks and gluons via $SU(3)_C$ symmetry. QCD contains features
¹⁴⁴ not present in Electroweak Interactions due to $SU(3)_C$ generators not commuting
¹⁴⁵ (a.k.a. $SU(3)_C$ is a non-abelian group). For example, in QCD there is color
¹⁴⁶ confinement and asymptotic freedom due to the structure constants being non-
¹⁴⁷ zero. Requiring $SU(3)_C$ local gauge invariance implies:

$$\psi(x) \rightarrow \psi(x)' = \exp[i g_S \alpha(x) \cdot \hat{T}] \psi(x) \quad (1.34)$$

¹⁴⁸ where $\alpha(x)$ is the local phase function, g_S is the strong coupling constant, and
¹⁴⁹ \hat{T} are the eight generators of $SU(3)$ (note $\hat{T}^a = \frac{1}{2}\lambda^a a$, where λ^a are the Gell-Mann
¹⁵⁰ matrices). As the Gell-Mann matrices are 3x3, this means ψ has three degrees of
¹⁵¹ freedom under these $SU(3)$ rotations. So we represent ψ under $SU(3)$ rotations
¹⁵² as:

$$\psi = \begin{pmatrix} \psi_{red} \\ \psi_{green} \\ \psi_{blue} \end{pmatrix} \quad (1.35)$$

¹⁵³ Consequently, particle fields transforming under $SU(3)$ rotations have three
¹⁵⁴ components which physicists describe as color components (red, green, and blue).
¹⁵⁵ A particle's corresponding antiparticle has the corresponding anticolor. This color
¹⁵⁶ is the "charge" of QCD and is conserved under $SU(3)$ rotations. Combining colors,
¹⁵⁷ color neutral states (e.g. red and antired, or red, green and blue) may be created.
¹⁵⁸ For the Free Dirac Lagrangian to remain invariant under $SU(3)$ transformations,
¹⁵⁹ we must again postulate a boson field that modifies the derivative. The gluon

₁₆₀ field tensor is given by ($\alpha = 1, \dots, 8$):

$$G_{\mu\nu}^k = \partial^\mu G_\alpha^\nu - \partial^\nu G_\alpha^\mu - g_S f^{\alpha\beta\gamma} G_\beta^\mu G_\gamma^\nu \quad (1.36)$$

₁₆₁ Here $f^{\alpha\beta\gamma}$ are the structure constants of $SU(3)$. Combining all this gives the
₁₆₂ QCD Lagrangian:

$$\mathcal{L}_{QCD} = \bar{\psi}_q i\gamma^\mu (D_\mu)_{ij} \psi^{qj} - m \bar{\psi}^{qi} \psi_{qi} - \frac{1}{4} G_{\mu\nu}^\alpha G^{\alpha\mu\nu} \quad (1.37)$$

₁₆₃ Here i are the color indices, and q are the quark flavors. It is important to
₁₆₄ note that quarks transform under the fundamental representation of $SU(3)$, while
₁₆₅ gluons transform under the adjoint representation. This means quarks carry a
₁₆₆ single color charge (red, green, blue, antired, antigreen, antiblue) and gluons carry
₁₆₇ a color and anticolor charge.

₁₆₈ Figure 1.3 shows the three dominant QCD interactions. Since gluons carry
₁₆₉ color charge, they interact with one another. This does not occur in QED, as
₁₇₀ photons do not have electric charge and therefore do not interact with each other.
₁₇₁ In QED, a bare electron's effective charge is largest closest to the electron and
₁₇₂ decreases as a function of distance. This is because the QED vacuum fills with
₁₇₃ particle antiparticle pairs spontaneously, which screen the charge of the bare elec-
₁₇₄ tron. The larger the distance from the electron, the smaller the effective charge
₁₇₅ and therefore the weaker the force. So for a pair of electrons, as the distance
₁₇₆ between them increases the repulsive force decreases and they may be observed
₁₇₇ separately.

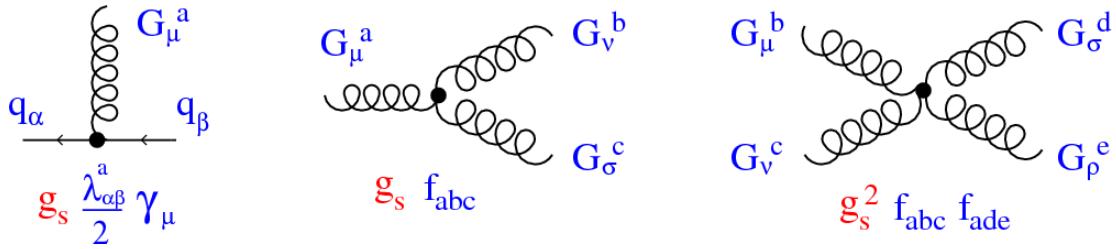

Figure 1.3: This figure shows the three dominant QCD interactions. From Ref. [14]

178 As the distance from a quark increases it's effective color charge increases due
 179 to the vacuum polarization in QCD. Color charge grows as the distance from
 180 the source increases (a.k.a. color is anti-screened in QCD). In this way, strong
 181 interactions become stronger at large distances (low momenta interactions). At
 182 small distances (large momenta interactions) strong interactions are significantly
 183 weaker and considered nearly free. This effect of referred to as asymptotic freedom.
 184 At large distances, a quark's effective charge is large and the strong force is more
 185 significant. This force becomes so strong that quarks form colorless bound states
 186 instead of remaining free particles. This effect is known as color confinement.
 187 This running of all SM fields is shown in Figure 1.4.

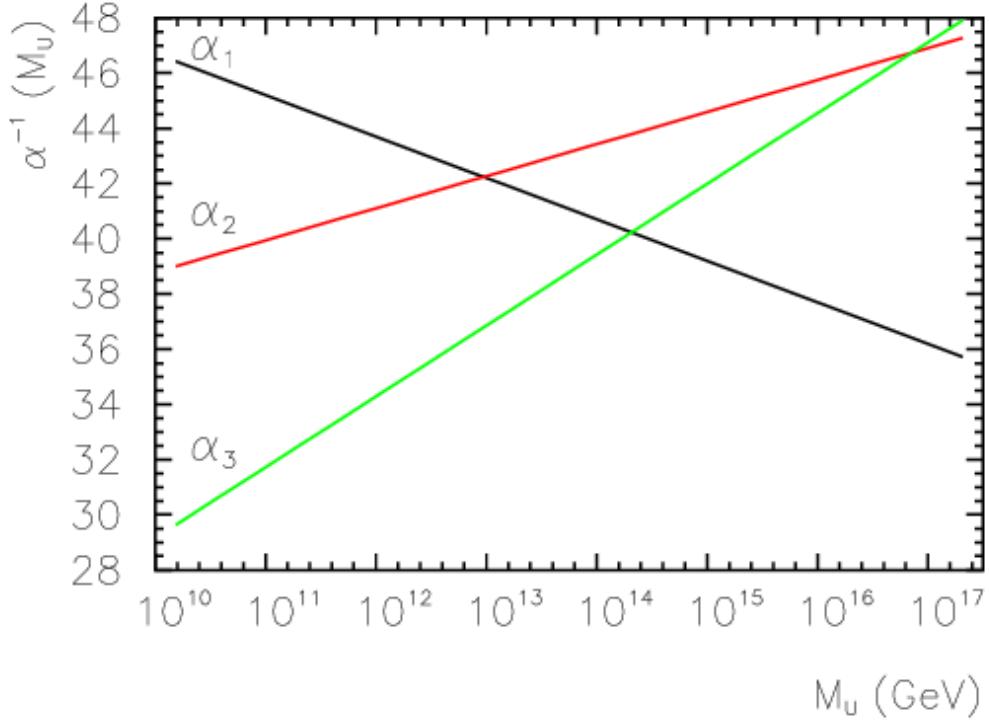

Figure 1.4: Strength of the U(1), SU(2), and SU(3) gauge couplings as a function of the energy scale of the interaction (Q). From Ref. [10]

Commonly the change in a particle's effective charge under a given force is quantified with $\beta(r) \equiv -\frac{de(r)}{d\ln r}$, where $e(r)$ is the effective charge of a given particle under a force. In QED this function is positive but in QCD this function is negative leading to confinement and asymptotic freedom. Moreover, one can calculate how the coupling (α) of a force varies with energies. (More deeply this amounts to incorporating renormalization and vacuum polarization in the boson propagators).

For QCD this is:

$$\alpha_S(x) = \frac{\alpha_S(\mu^2)}{1 + \beta_0 \alpha_S(\mu^2) \ln(Q^2/\mu^2)} \quad (1.38)$$

195

$$\beta_0 = \frac{11N_c - 2n_f}{12\pi} \quad (1.39)$$

196 where Q is the momentum of the force is probed at, μ^2 is the renormalization scale.

198 As stated previously, quarks and gluons have not been observed in isolation.
199 Instead they form bound colorless states. Hadronization is the process by which
200 quarks and gluons form hadrons. The process of hadronization is still an active
201 area of research. One qualitative description is shown in Figure BLAH. In this
202 figure, as two quarks separate the color field between them is restricted to a tube
203 with energy density of ~ 1 GeV/fm. As they separate further, the energy in the
204 color field increases, until there is enough energy to produce $q\bar{q}$ pairs, which breaks
205 the color field. This process repeats until quarks and antiquarks have low enough
206 energy to form colorless hadrons. The resulting spray of hadrons is called a jet.

207 Since quarks and gluons carry different color charges, their respective jets have
208 different properties. As quarks carry only a single color charge (vs. gluons which
209 have color and anticolor charge), so their jets have less constituent particles. More
210 precisely, the Altarelli-Parisi splitting functions [3] contain a factor C_A for gluon
211 radiation off a gluon and C_F for gluon radiation off a quark ($C_A/C_F = 9/4$). These
212 color factors are the prefactor in the Feynman diagrams for these processes [1],
213 which leads to gluon jets having more constituents and therefore more tracks than
214 quark jets. Gluon jets also tend to have a larger radius with lower momentum
215 constituents than quarks. There are many novel techniques to distinguish quarks
216 from gluons. For this study the number of charged particles will be focused on.

₂₁₇ **Chapter 2**

₂₁₈ **Standard Model Successes and**

₂₁₉ **Limitations**

₂₂₀ The Standard Model has consistently described much of reality to an extreme
₂₂₁ degree of accuracy. It has predicted cross sections for strong and electroweak
₂₂₂ processes that span over ten order of magnitude correctly [see Fig 2.1] and contains
₂₂₃ no known logical inconsistencies. Despite the strength and reality of the Standard
₂₂₄ Model, it still fails to describe aspects of reality and suffers from aesthetic issues.
₂₂₅ To date, dark matter and energy comprise $\sim 95\%$ of the universe, but are not
₂₂₆ accounted for in the SM. Additionally, neutrinos are known to have mass but are
₂₂₇ massless in the SM. There are mechanisms for introducing massive neutrinos in
₂₂₈ the SM, but these mechanisms create hierarchy problems.

₂₂₉ Possibly the most significant aesthetic issue is the hierarchy between the elec-
₂₃₀ troweak and Planck scales. The electroweak scale is the scale of electroweak
₂₃₁ symmetry breaking. The Planck scale is the scale where the gravitational force
₂₃₂ is comparable in strength to the other forces. (This is also the scale where the
₂₃₃ gravitational potential energy of two objects separated by a distance r is equal to
₂₃₄ the energy of a photon with a wavelength r .) The Planck scale is where the SM

235 breaks down, as there is not an experimentally verified theory of quantum gravity,
236 and at this scale gravity cannot be ignored (like it can at the electro-weak scale).
237 These scales differ by ~ 30 orders of magnitude. Understanding the difference
238 in these energy scales, may help explain the weakness of gravity at electroweak
239 scales, and possibly a QFT for gravity. (NB: This hierarchy can also be framed in
240 terms of the corrections to the Higgs mass, which depend on the UV cutoff scale -
241 where the SM is suppose to break, which is taken at the Planck scale. This leads
242 the quantum corrections to the Higgs mass to force the Higgs mass to $\sim 10^{18}$
243 TeV.)

244 These stark contrasts in scales may indicate that a more fundamental theory
245 exists. It is hoped that such a theory would explain and motivate some of the ad-
246 hoc features of the SM. In particular, there currently are no experimentally verified
247 explanations of why there are three generations of fermions, the values of the 19
248 SM parameters (6 quark masses, 3 charged lepton masses, 3 gauge couplings,
249 Higgs parameters (μ^2, λ)), the structure of the fermion representations, etc.

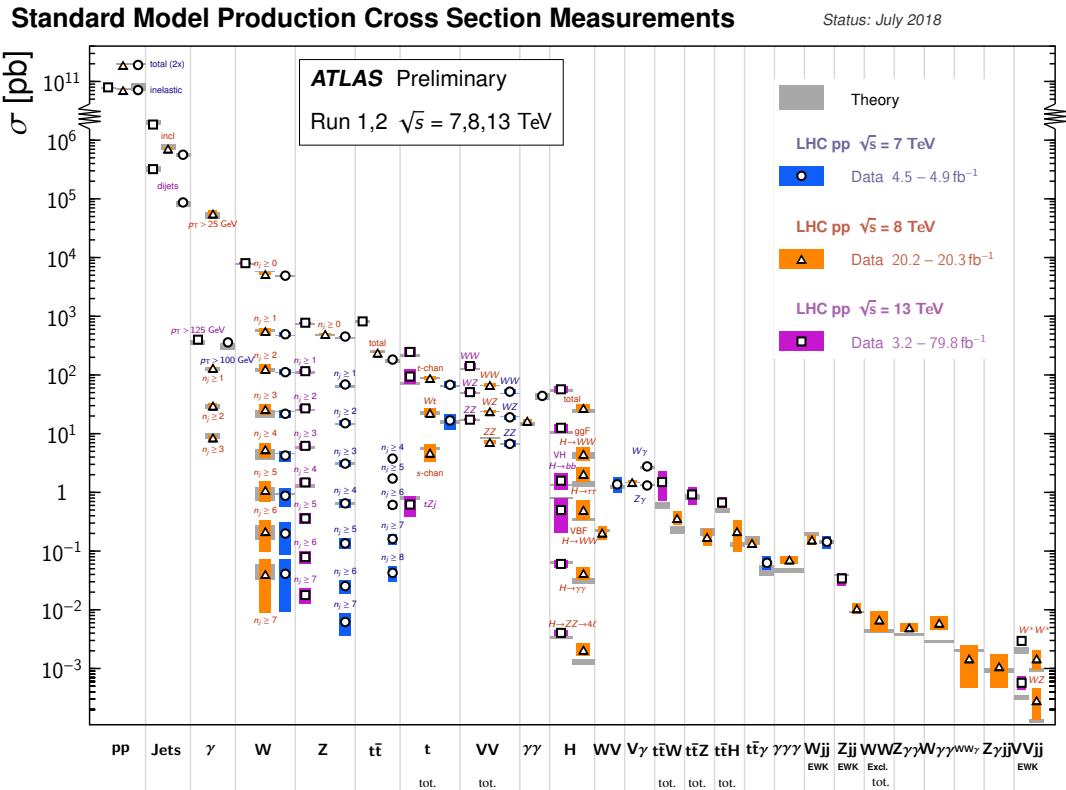

Figure 2.1: A comparison of cross section measurements at $\sqrt{s} = 7,8,13$ TeV from ATLAS compared to theoretical measurements. From Ref. [5]

250 **Chapter 3**

251 **New Physics Models with
252 Diboson Resonances**

253 **3.1 Randall Sundrum Bulk Model**

254 The electroweak-planck hierarchy may be explained by the existence of extra
255 dimensions, like the 5D Randall Sundrum Bulk Model ([15], [2]). In this model,
256 there is one extra warped spatial dimension, y , with a metric:

$$ds^2 = e^{-2k|y|} \eta_{\mu\nu} dx^\mu dx^\nu + dy^2 \quad (3.1)$$

257 where $e^{-k|y|}$ is the warp factor of the extra dimension, which is compactified on
258 a S^1/Z_2 orbifold (a.k.a. a circle where $y \rightarrow -y$). This can be visualized as every
259 point in space time having a line extending from it a distance L , representing
260 this fifth dimension. At the end of this line is the Planck brane. This fourth
261 spatial dimension separates two 4-D branes: Planck brane and TeV brane. We
262 live on the TeV brane, as shown in Figure 3.1. The Higgs field (and to a lesser
263 degree the top quark and graviton fields) is localized near the TeV Brane, while

264 the light fermion fields are localized more near the Planck brane. Fundamental
 265 parameters are set on the Planck brane. The warp factor may be scaled away from
 266 all dimensionless SM terms by field redefinitions. However, the only dimensionful
 267 parameter, $m_H^2 = v^2$ is rescaled by $\tilde{v} \sim e^{-kL} M_{Pl} \sim 1\text{TeV}$ for $kL \sim 35$, explaining
 268 why gravity is so weak on the TeV brane. Also, by localizing the light fermion
 269 fields near the Planck brane and top and graviton fields near the TeV brane, the
 270 light quarks will have smaller masses.

271 The two free parameters of this theory are M_{Pl} and k . Based on this RS Bulk
 272 model, all SM particles should have Kaluza-Klein (KK) excitations. In particular,
 273 the graviton would have KK excitations that prefer to decay to WW or ZZ, which
 274 is why this analysis searches for RS Gravitons.

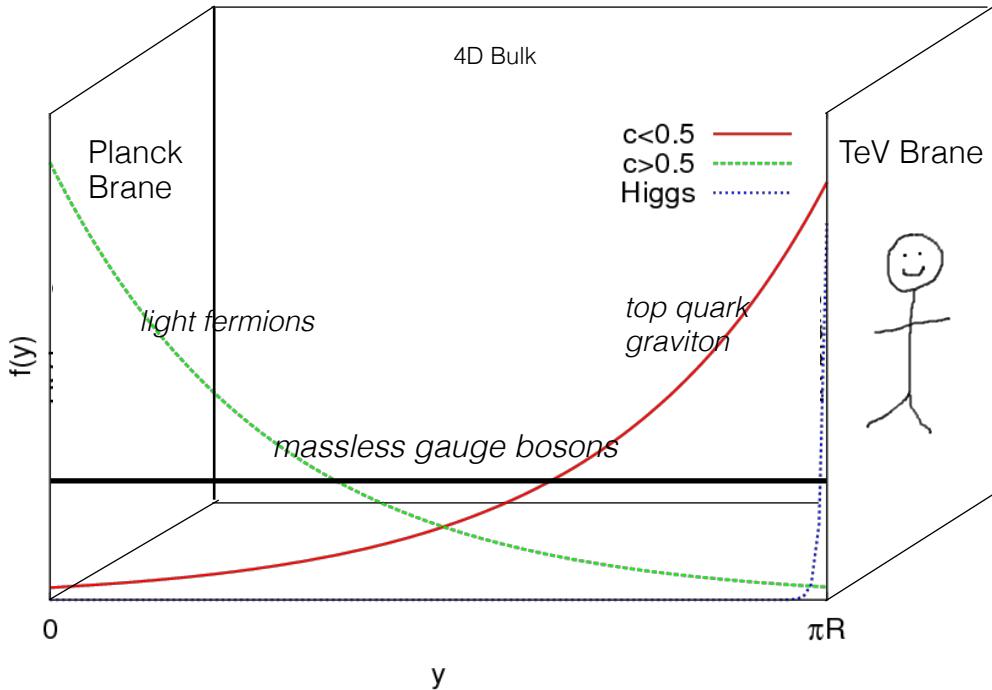

Figure 3.1: Cartoon of RS Bulk Model

²⁷⁵ **3.2 Extended Scalar Sector**

²⁷⁶ A further striking asymmetry of the SM is the simplicity of the scalar sector in
²⁷⁷ comparison to the boson and fermion sectors. To date, the scalar sector has only
²⁷⁸ one member, the Higgs boson. Therefore, it is natural to posit an extension to the
²⁷⁹ scalar sector. From a theoretical standpoint this could also help generate baryon
²⁸⁰ asymmetry through additional sources of CP violation. This analysis searches for
²⁸¹ a simple extension to the scalar sector as proposed in Ref. [16]. The extended
²⁸² scalar sector includes a real Higgs singlet (S) and complex $SU(2)_L$ doublet (Φ)
²⁸³ (the SM Higgs), where mass eigenstates are mixtures of the fields. S has a vev of
²⁸⁴ v and Φ has a vev of x . This then gives a Lagrangian of:

$$\mathcal{L} \supset (D^\mu \Phi)^\dagger D_\mu \Phi + \partial^\mu S \partial_\mu S - m^2 \Phi^\dagger \Phi - \mu^2 S^2 + \lambda_1 (\Phi^\dagger \Phi)^2 + \lambda_2 S^4 + \lambda_3 \Phi^\dagger \Phi S^2 \quad (3.2)$$

²⁸⁵ The mass eigenstates of the scalar sector are then mixtures of S and Φ and
²⁸⁶ the free parameters of the theory are m_H , $\sin \alpha$, and $\tan \beta = v/x$. The fields are
²⁸⁷ then given by:

$$\Phi \equiv \begin{pmatrix} 0 \\ \frac{\tilde{h}+v}{\sqrt{2}} \end{pmatrix} \quad (3.3)$$

$$S \equiv \frac{h' + x}{\sqrt{2}} \quad (3.4)$$

²⁸⁸ Diagonalizing the mass matrix leads to the mass eigenstates h (discovered
²⁸⁹ Higgs boson) and H (the physical particles):

$$\begin{pmatrix} h \\ H \end{pmatrix} = \begin{pmatrix} \cos \alpha & -\sin \alpha \\ \sin \alpha & \cos \alpha \end{pmatrix} \quad (3.5)$$

291 This suppressed h and H production and SM H couplings:

$$BR_{H \rightarrow SM} = \sin^2 \alpha \times \frac{\Gamma_{SM, H \rightarrow SM}}{\Gamma_{tot}} \quad (3.6)$$

292 Moreover, in the case that $m_H > m_h$, $H \rightarrow hh$ is possible. This further suppresses
293 $H \rightarrow VV/ff$. This search is most sensitive to $H \rightarrow WW$.

294 3.3 Simple Standard Model Extensions

295 The RS Bulk model is motivated by resolving the hierarchy problem. Ex-
296 tending the Scalar sector is a natural space to look for new physics due to the
297 complexity of fermion and boson groups. There are many other interesting and
298 well motivated frameworks, but there is a lack of completely predictive models,
299 due to model flexibility (free parameters). Therefore it is hard for experimentalists
300 to know which theories to search for in data. However, as seen in [13], a "Simpli-
301 fied Model" approach may be taken. In the search for reasonably narrow width
302 particles, as in this search, the search is not sensitive to all the details and free
303 parameters of the theory. Generally such searches are only sensitive to the reso-
304 nance mass and its interactions. Therefore, a theory's Lagrangian may be reduced
305 to only retain this information (mass parameters and couplings). Experimental
306 results using this framework may then be reinterpreted in a given theory.

307 In the simplified approach, the new resonance searched for is represented as
308 a real vector field in the adjoint representation of $SU(2)_L$ with vanishing hyper-
309 charge. This results in one neutral and two charged bosons. Defined as:

$$V^\pm = \frac{V_\mu^1 \mp iV_\mu^2}{\sqrt{2}} \quad (3.7)$$

310 $V_\mu^0 = V_\mu^3 \quad (3.8)$

311 The SM Lagrangian is then augmented with the additional terms:

$$\mathcal{L} \supset -\frac{1}{4}D_{[\mu}V_{\nu]}^a D^{[\mu}V^{\nu]}_a + \frac{m_V^2}{2}V_\mu^a V^{a\mu} + ig_V c_H V_\mu^a H^\dagger \tau^a \overset{\leftrightarrow}{D}^\mu H + \frac{g^2}{g_V} c_F V_\mu^a J_F^{\mu a} \quad (3.9)$$

312 In order the terms represent: the kinetic, V mass, Higgs- V interaction, and
313 V -left-handed fermion interaction terms. Phenomenologically the three physical
314 particles this predicts are degenerate, where V couples most strongly to VV , via
315 the g_V coupling factor. The dominant production modes are DY and VBF.

316 Two versions of HVT are considered, Model A and B. Model A is a weakly
317 coupled model where $g_V \sim 1$, like the extended gauge symmetry discussed in Ref .
318 [16]. Model B is a strongly coupled model, where $1 < g_V < 4\pi$. The width of the
319 resonance grows with g_V so for this narrow resonance search only g_V is chosen to
320 be less than 6 (so $\Gamma/M < 10\%$). More precisely, the coupling of these resonances
321 to fermions scales as $g_f = g^2 c_F/g_V$, where g is the SM $SU(2)_L$ gauage coupling
322 and c_F is the free parameter (expected to be of order 1 for Model A and B). This
323 then means that for Model B the coupling is to fermions is more suppressed than
324 for Model A, leading to a smaller DY production rate and BR to fermionic final
325 states. The coupling of V to SM bosons scales as $g_H = g_V c_H$, where c_H is a
326 free parameter on the order of 1 for Model A and B. So for small values of g_V
327 (i.e. Model A - weakly coupled theories) the BR to gauge bosons is smaller than
328 for Model B. So weakly coupled vectors have large production cross sections and
329 decay prominantly to leptons or jets, while strongly coupled vectors are produced
330 less and decay predominantly to gauge bosons.

331 Vectors in Model A and B are generally produced via quark-anti-quark annihi-
332 lation. The more rare production via vector-boson-fusion is considered by setting
333 $g_H = 1$ and $g_F = 0$. In Model B diboson final states are enhanced as stated
334 previously due to g_H and moreover the BR to WZ , WH , WW , and ZH are the

³³⁵ same.

³³⁶ In summary, V couples most strongly to left-handed fermions and VV dependent on g_V .

Part II

339

Experimental Setup

³⁴⁰ **Chapter 4**

³⁴¹ **LHC**

³⁴² The Large Hadron Collider (LHC) is the highest-energy particle collider in the
³⁴³ world. It was designed to expand the frontier of high energy particle collisions in
³⁴⁴ energy and luminosity. This enables LHC experiments to test the Standard Model
³⁴⁵ and search for new physics at higher energies than tested with previous colliders.
³⁴⁶ Collisions at higher energies not only produce more massive particles but also
³⁴⁷ more weakly interacting particles. Fig. 4.1 shows production cross sections for
³⁴⁸ various processes at hadron colliders. The rate for electroweak physics pcoesses
³⁴⁹ including W and Z scale with the center-of-momentum energy, \sqrt{s} .

³⁵⁰ The LHC consists of a 26.7 km (17 miles) ring, approximately 100 m un-
³⁵¹ derground, outside Geneva, Switzerland. Counter-circulating proton (and occa-
³⁵² sionally heavy ions) beams collide inside four experiments along the beam line:
³⁵³ ATLAS, CMS, LHCb, ALICE. ATLAS and CMS are general purpose detectors
³⁵⁴ designed to explore high energy frontier. LHCb is designed to study the physics
³⁵⁵ of b -quarks. ALICE specializes in studying heavy ion collisions.

proton - (anti)proton cross sections

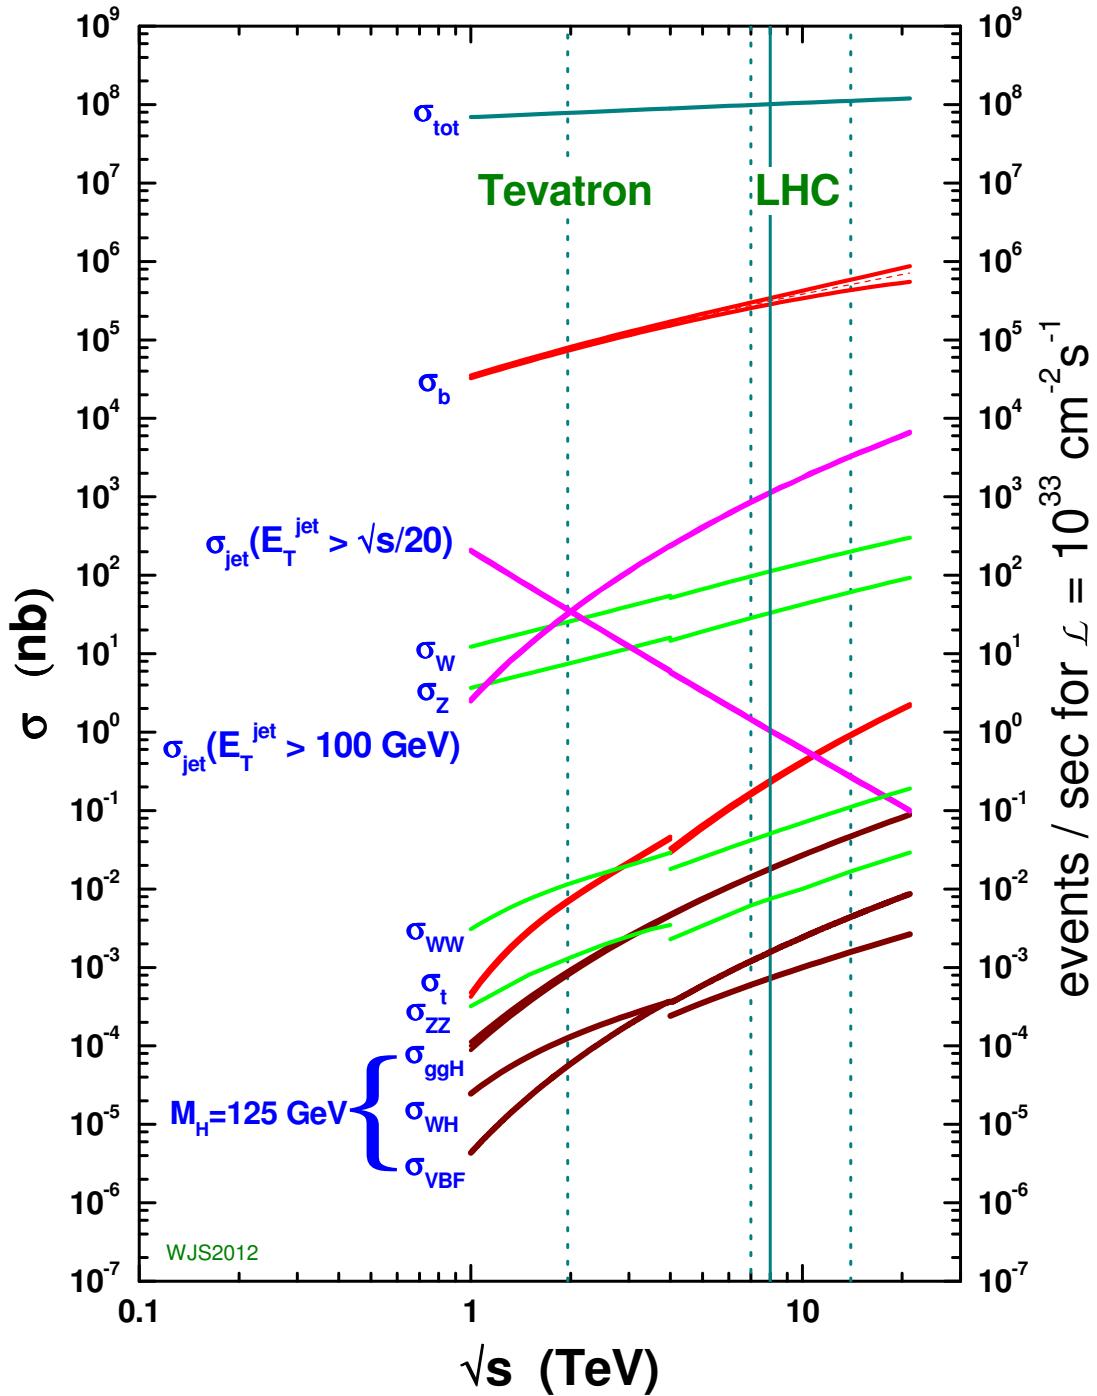

Figure 4.1: Scaling of cross sections with \sqrt{s} . Natasha: write more here

356 The first proton beams circulated in September, 2008. Nine days later an elec-
357 trical fault lead to mechanical damage and liquid helium leaks in the collider. This
358 incident delayed further operation until November 2009, when the LHC became
359 the world's highest energy particle collider, at 1.18TeV per beam. This first oper-
360 ational run continued until 2013, reaching 7 and 8 TeV collision energies. During
361 this run a particle with properties consistent with the Standard Model Higgs bo-
362 son was discovered. The next run began after a two year shutdown after upgrades
363 to the LHC and experiments. This run lasted from 2013 to 2018 reaching 13 TeV
364 collision energies. This analysis uses data from the second operational run.

365 **4.1 LHC Layout and Design**

366 The layout of the LHC is shown in Figure 4.2. The red and blue lines in the
367 figure represent the counter-circulating proton beams. The LHC is divided into
368 eight octants. Octant 4 contains the RF cavities that accelerate the protons and
369 octant 6 contains the beam dump system. Octants 3 and 7 house the collimation
370 systems for beam cleaning. The beams collide inside the four aforementioned
371 experiments. Each octant contains a curved and straight section. The LHC
372 magnets are built with NbTi superconductors cooled with super-fluid Helium to
373 2K, creating a 8.3T magnetic field to bend the proton beams.

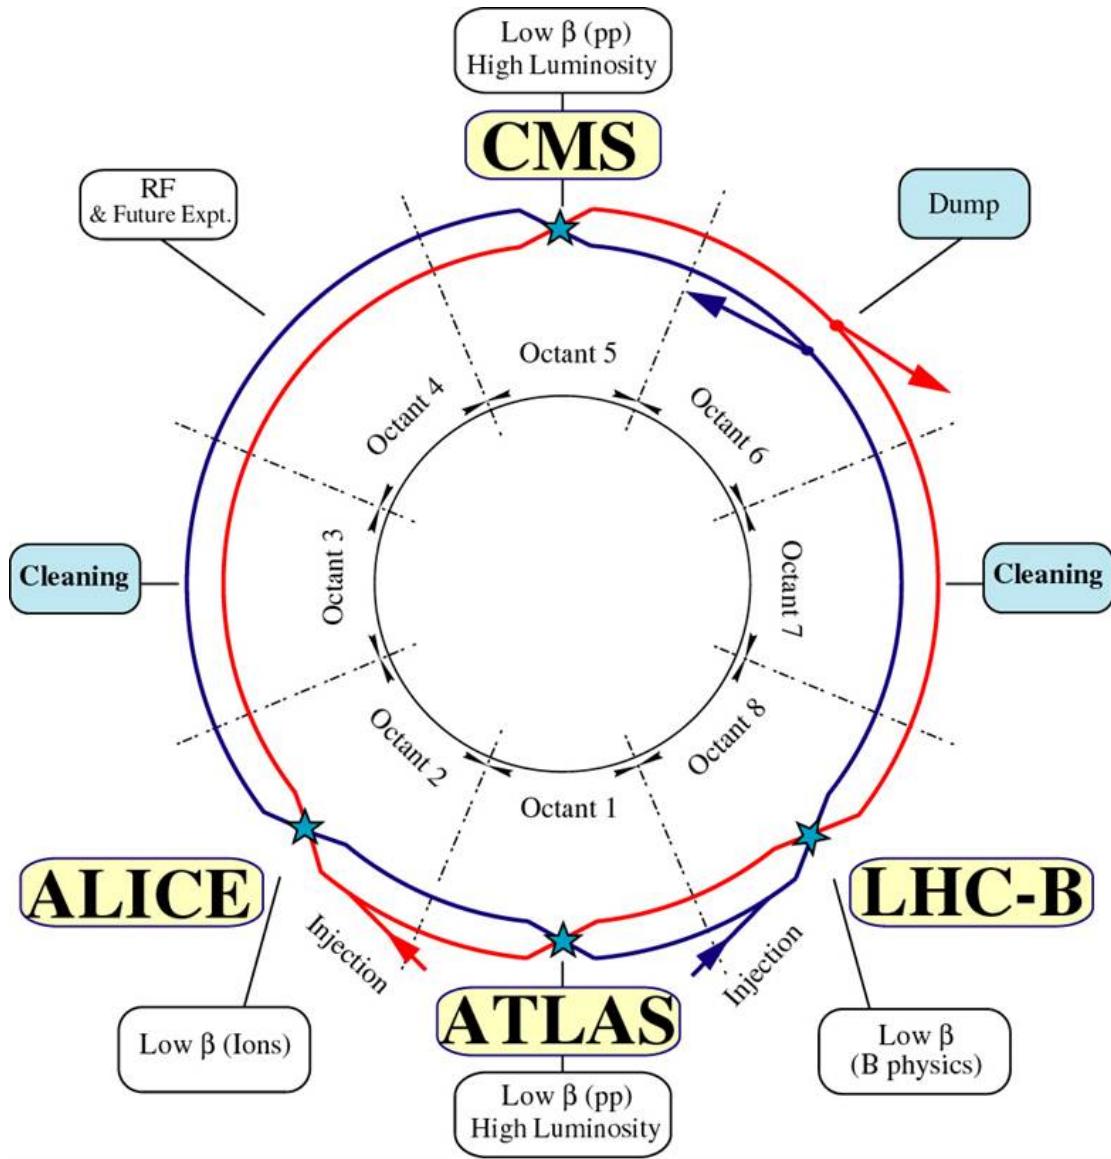

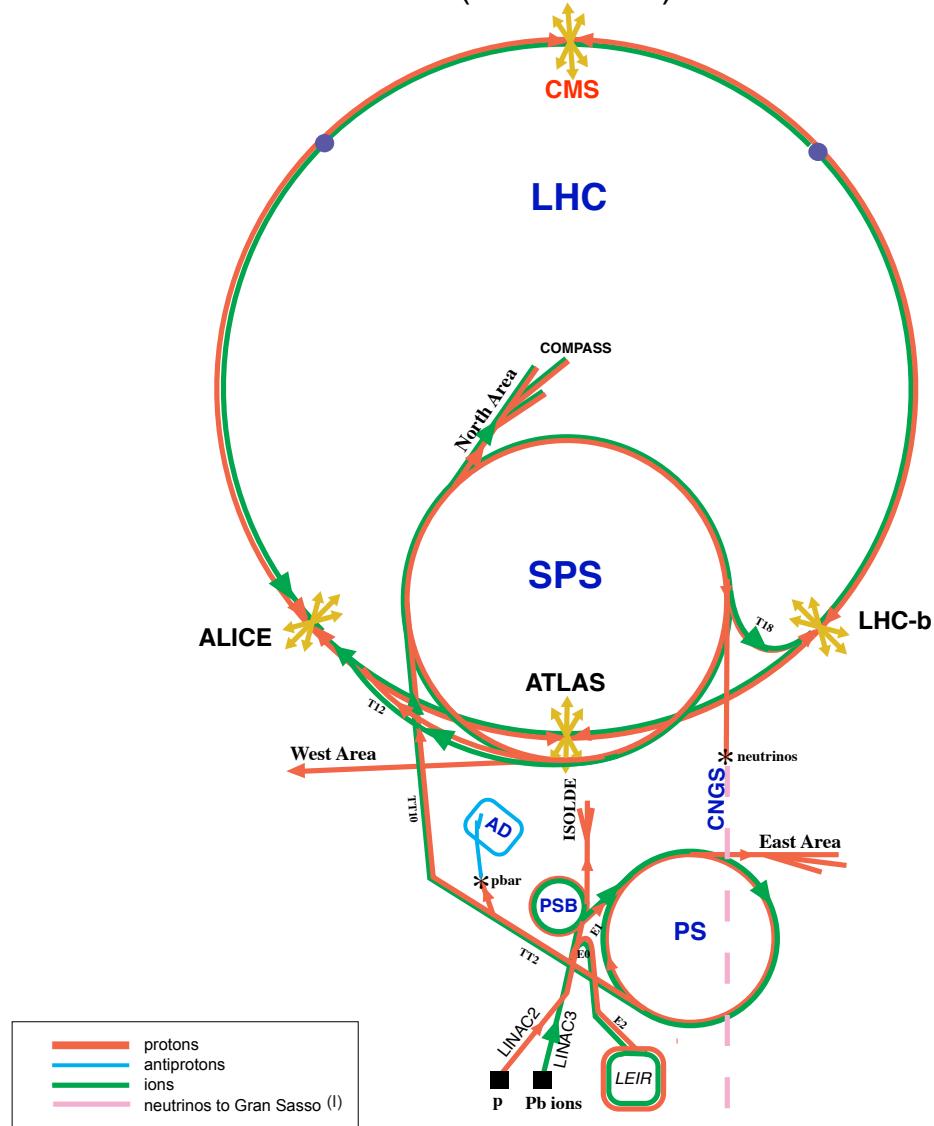

Figure 4.2: LHC Layout. Natasha write more

374 Four sequential particle accelerators are used to accelerate proton from rest
 375 as shown in Figure 4.3. First, Hydrogen gas is ionized to produce protons which
 376 are then accelerated to 50 MeV using Linac 2, a linear accelerator. The result-
 377 ing proton beam is then passed to three circular particle accelerators: Proton
 378 Synchrotron Booster, Proton Synchrotron, and Super Proton Synchrotron (SPS),

³⁷⁹ accelerating protons to 1.4, 25, and 450 GeV, respectively. Once the protons exit
³⁸⁰ SPS, they are injected into the LHC at octant 2 and 8. Each proton bunch contains
³⁸¹ $\sim 10^{11}$ protons. The spacing between bunches is 25 ns, which means each beam
³⁸² contains 3564 bunches. However, some bunches are left empty due to injection
³⁸³ and safety requirements, yielding 2808 bunches per beam. Once the proton beams
³⁸⁴ are injected they are accelerated to 13 TeV.

Figure 4.3: LHC Accelerator. Natasha write more

385 As many new physics models predict cross-sections below the weak scale it was
386 important to design the LHC to be capable of collecting enough data, by running
387 in high luminosity conditions. The machine luminosity depends only on beam
388 parameters:

$$L = \frac{N_p^2 f}{4\epsilon\beta^*} F \quad (4.1)$$

389 where N_p is the number of protons per bunch, f is the bunch crossing frequency,
390 ϵ is the transverse beam emittance, β^* is the amplitude function at the collision
391 point, and F is the geometric luminosity reduction factor due to the beams crossing
392 at an angle (rather than head-on).

³⁹³ **Chapter 5**

³⁹⁴ **The ATLAS Detector**

³⁹⁵ The ATLAS detector measures the position, momentum and energy of parti-
³⁹⁶ cles produced in the proton collisions by using magnetic fields, silicon detectors,
³⁹⁷ sampling calorimeters, and gaseous wire detectors. It is located approximately
³⁹⁸ 100 m underground at Point-1 around the LHC beam line and weighs 7000 metric
³⁹⁹ tons. The detector is 46 m long, 25 m high, 25 m wide as shown in Figure 5.2.
⁴⁰⁰ The detector can be divided into three subsystems: the Inner Detector (ID), the
⁴⁰¹ Calorimeters, and the Muon Spectrometer (MS). Figure 5.3 shows an overview of
⁴⁰² how different particles interact in the detector.

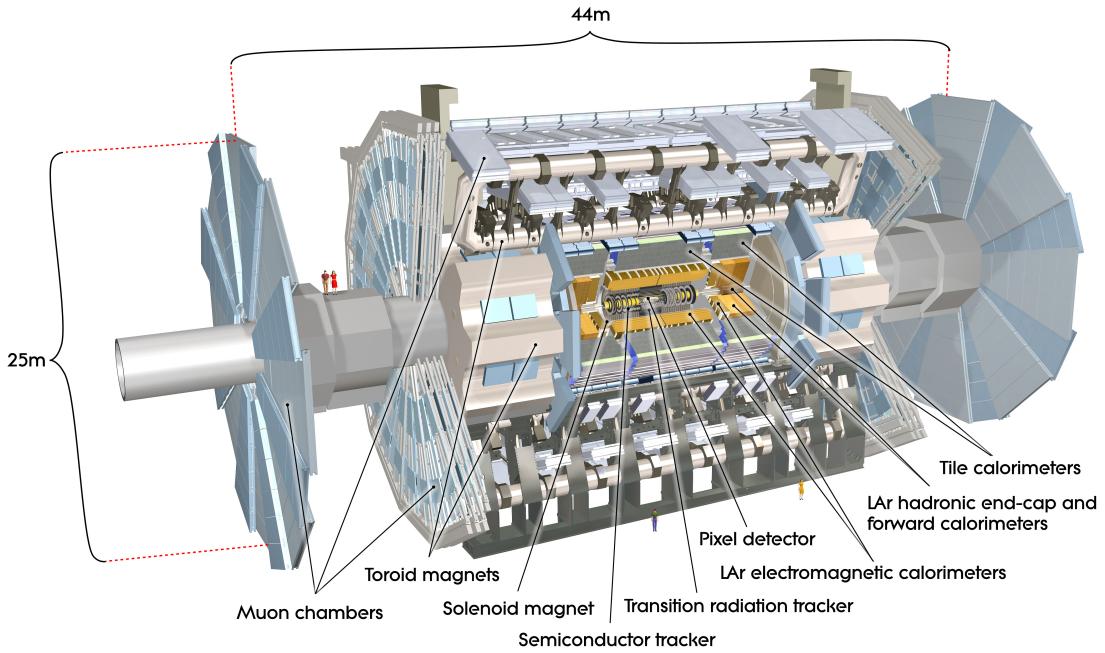

Figure 5.1: Big picture layout of ATLAS detector. Natasha: write more

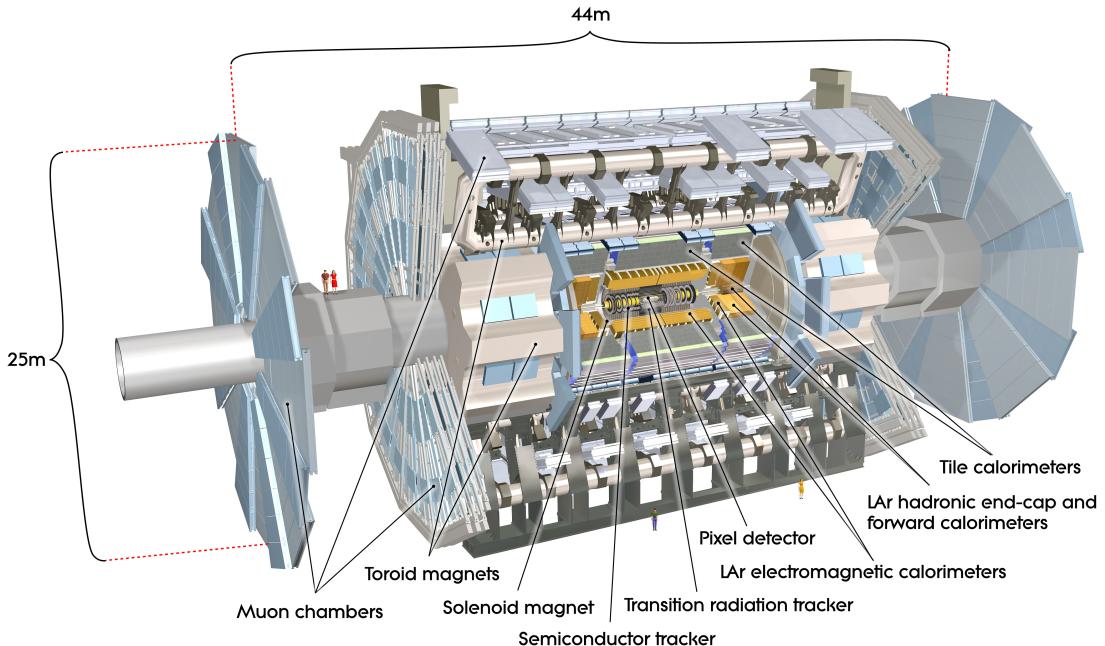

Figure 5.2: Big picture layout of ATLAS detector. Natasha: write more

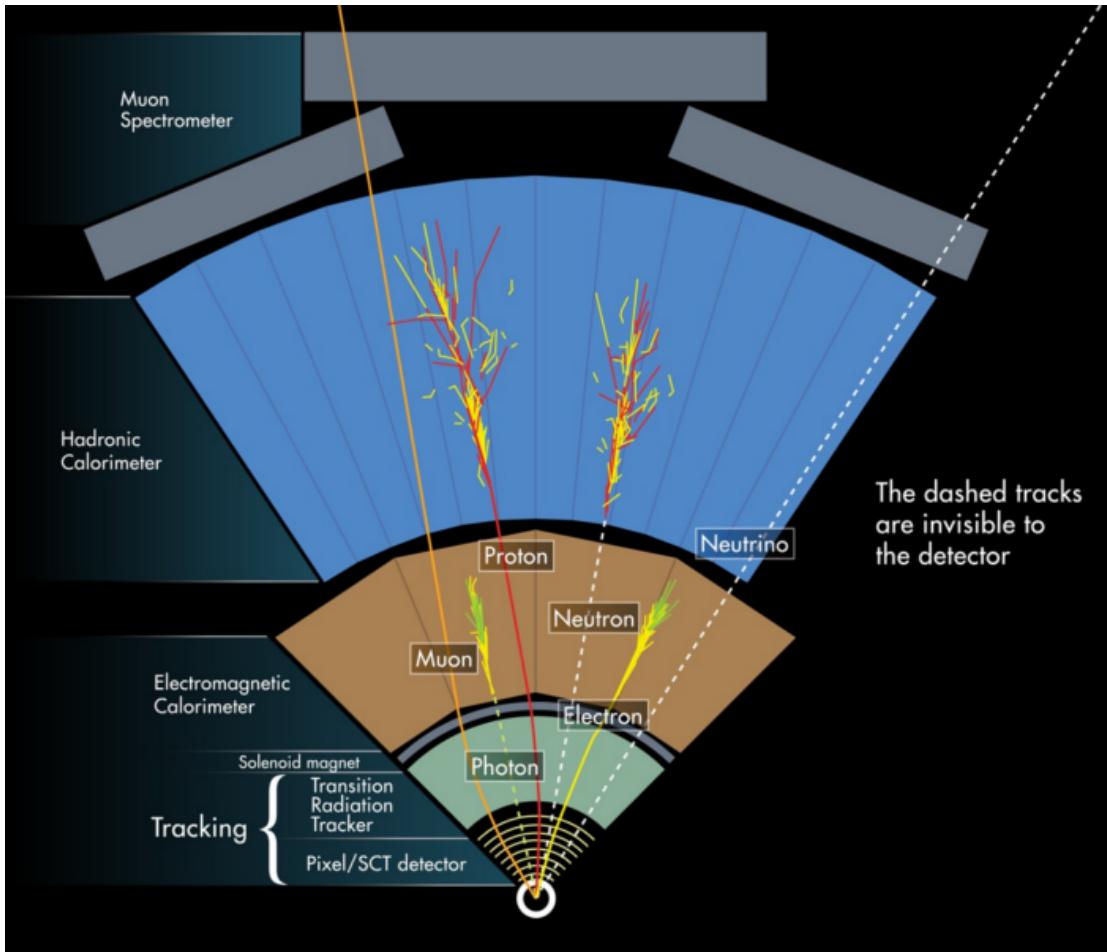

Figure 5.3: A simplified schematic of how different particles interact and are detected within ATLAS.

403 5.1 Coordinate System

404 The trajectory of particles within ATLAS is measured relative to the nominal
 405 interaction point. The z -axis points along the beam line, such that when the
 406 LHC is viewed from above, the counter-clockwise circulating beam points along
 407 the positive- z direction. The $x - y$ plane is transverse to the beam line, with the
 408 positive x -axis pointing towards the center of the LHC ring. The positive y -axis
 409 points vertically upward. The azimuthal angle, ϕ , is the angular distance about

410 the z -axis, with $\phi = 0$ along the x -axis. The polar angle from the z -axis is denoted
411 as θ . However, this quantity is not Lorentz invariant, like rapidity, $y = \frac{1}{2} \ln \frac{E+p_z}{E-p_z}$,
412 where E is the energy of the particle considered, and p_z , is it's momentum along
413 the z -axis. Pseudo-rapidity is preferred as $\Delta\eta$ is invariant under boosts along z
414 and particle production is approximately invariant under η . For massless particles,
415 rapidity and a related quantity, pseudorapidity, are the identical. The pseudora-
416 pidity is defined as: $\eta = -\ln \tan(\frac{\theta}{2})$. This quantity is preferred as it is purely a
417 geometric quantity, independent of particle energy. Angular separation between
418 particles in ATLAS are given by $\Delta R = \sqrt{\Delta\eta^2 + \Delta\phi^2}$. The distance from the
419 beamline is given by $r = \sqrt{x^2 + y^2}$

420 5.2 Inner Detector

421 The Inner Detector (ID) was designed to identify and reconstruct vertices,
422 distinguish pions from electrons, and measure the momentum of charged particles.
423 The ID uses three different technologies for particle reconstruction: the Pixel
424 Detector, Semiconductor Tracker (SCT), and the Transition Radiation Tracker
425 (TRT), shown in Figure 5.4 and 5.5. The entire ID is immersed in a 2T solenoidal
426 magnetic field parallel to the $+z$ -axis, causing charged particles to bend in the
427 transverse-plane, allowing particle momentum measurements.

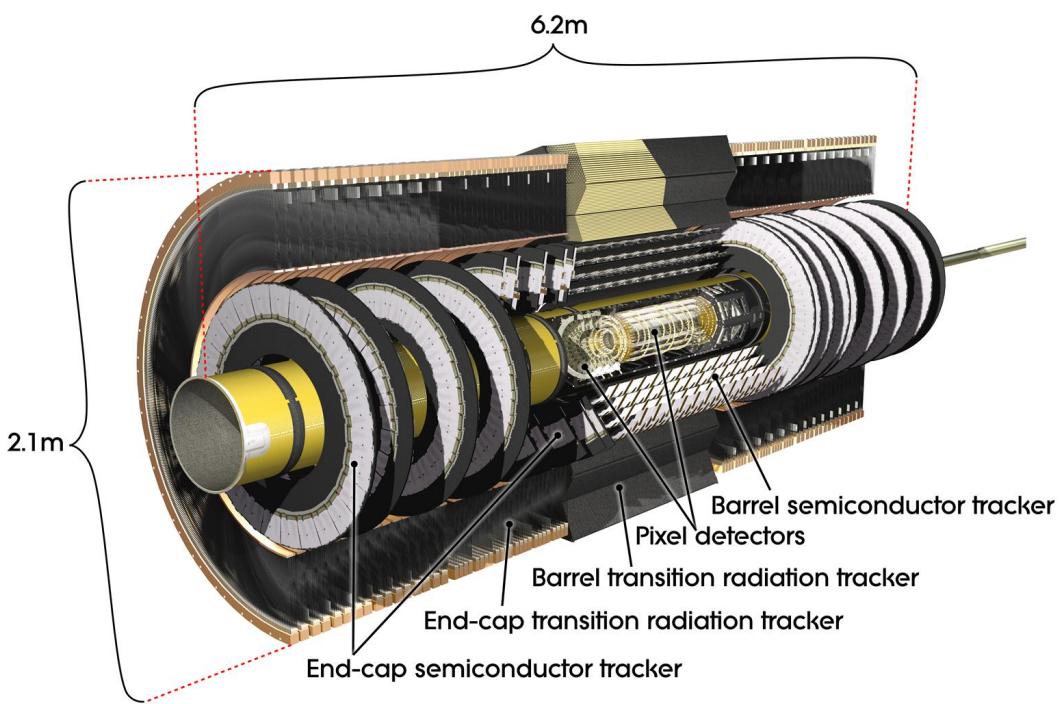

Figure 5.4: Layout of ATLAS Inner Detector

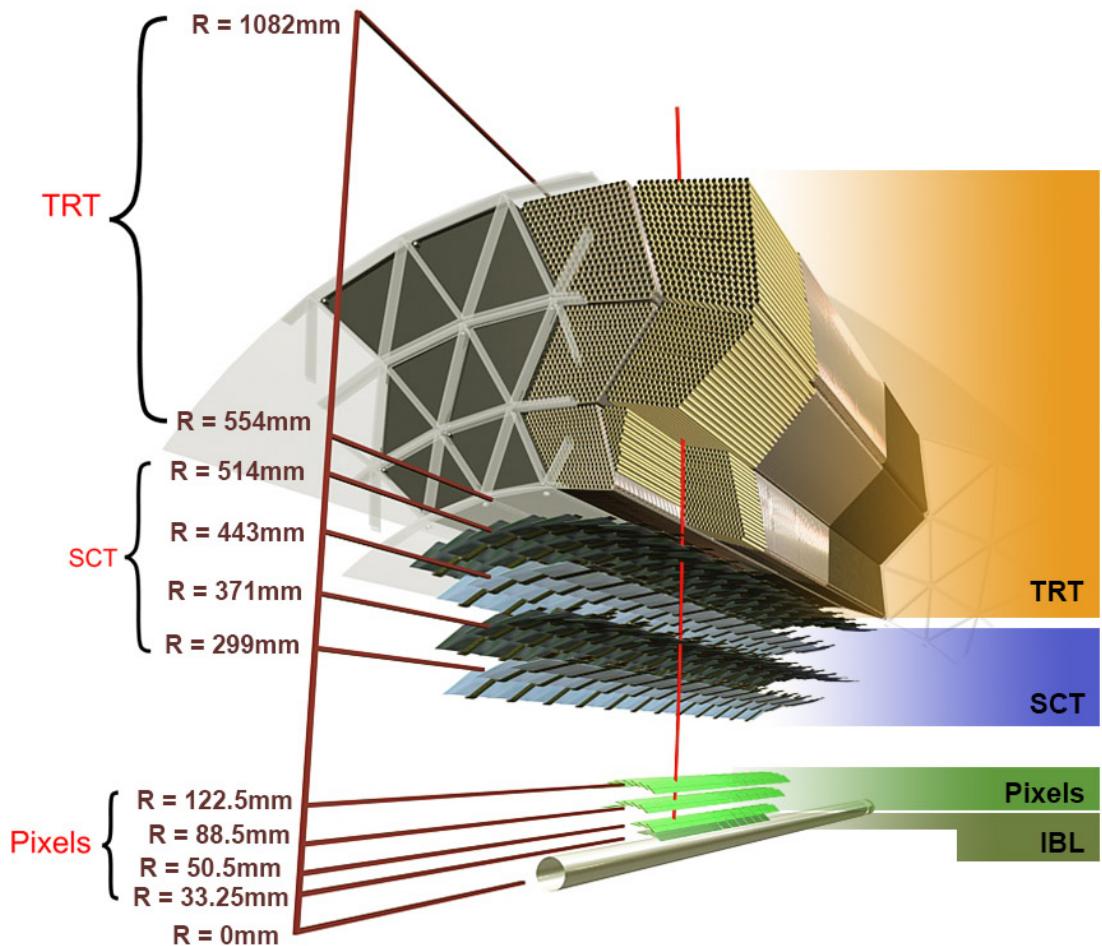

Figure 5.5: Layout of ATLAS ID Barrel System.

428 **5.2.1 Pixel Detector**

429 The pixel detector consists of four barrel layers between $r = 32.7$ and 122.5
430 mm, extending to $|z| = 400.5$ mm. The innermost pixel barrel, the Insertable
431 b-Layer (IBL), only extends to $|z| = 332$ mm. The pixel detectors closer to
432 the beam line (larger η values) consists of six parallel cylindrical rings of pixel
433 detectors transverse to the beam line. The entire pixel detector consists of 1744
434 identical pixel sensors each with 46080 readout channels, totaling about 80 million
435 individual pixels. Most of the pixel sensors are $50 \times 400 \mu\text{m}^2$. Each pixel has a
436 position resolution of $14 \mu\text{m}$ in ϕ and $115 \mu\text{m}$ in the z direction.

437 **5.2.2 Semiconductor Tracker**

438 The SCT is located outside the pixel detector and has the same barrel and
439 endcap geometry as the pixel detector. SCT sensors are $80 \mu\text{m} \times 12$ cm with
440 a $80 \mu\text{m}$ strip pitch. In the barrel the strips are parallel to the z -axis and are
441 segmented in ϕ . In the endcaps, the strips extend radially. Sensors are grouped in
442 modules containing two layers of strips rotated 40 mrad with respect to each other.
443 This offset allows for the two-dimensional position of a track to be determined by
444 identifying the crossing point of the strips that registered a hit. SCT modules
445 measure tracks with an accuracy of $17 \mu\text{m}$ in $r - \phi$ and $580 \mu\text{m}$ in $z(r)$ in the
446 barrel (end-cap) region.

447 **5.2.3 Transition Radiation Tracker**

448 The transition radiation tracker (TRT), enveloping the SCT, is a gaseous
449 straw-tube tracker mainly used for electron/pion track separation. Each straw
450 is 4 mm in diameter and filled with a Xe- CO_2 - O_2 gas mixture. An anode wire
451 at the center of the straw is held a ground potential, while the walls of the straw

452 are kept at -1.4kV. When a charged particle passing through the TRT ionizes the
453 gaseous mixture, the resulting ions form an avalanche on the anode wire with a
454 gain of $\sim 10^4$. The signal from the anode wire is then digitized and amplified.
455 Signals passing a low threshold cutoff are used to distinguish noise from tracks.
456 Signals passing a high threshold cutoff are sensitive to transition radiation (TR).
457 TR photons are emitted when charged particles pass between materials with dif-
458 ferent dielectric constants. The probability that a charged particle with energy E
459 and mass m passing between two materials emits a TR photon in the keV range
460 is proportional to $\gamma = E/m$. In the TRT straws these often then convert via the
461 photoelectric effect, causing a large avalanche triggering the high-threshold. Since
462 electrons have a smaller mass than pions, electron tracks are more likely to trig-
463 ger the high threshold. This then provides discrimination between electrons and
464 charged hadrons.

465 The barrel region of the TRT extends from $r = 563\text{-}1066$ mm and $|z| < 712$
466 mm. Barrel Straws are 144 cm long (divided $\sim \eta \approx 0$) and orientated parallel to
467 the beam direction. End-cap straws extend radially and are 37 cm long. There
468 are 53,544 straws in the barrel and 160,000 straws in the end-caps. Radiator mats
469 of polypropylene/polyethylene fibers in the barrel are aligned perpendicular to the
470 barrel straws (with holes for the straws to pass through). In the end-cap region,
471 radiator foils are layered between the radial TRT straws.

472 The width of the signal pulse is sensitive to the distance between the charged
473 particle track and the anode wire and allows for a hit resolution of $130\mu\text{m}$. The
474 TRT extends to $|\eta| = 2.0$ and provides about 36 hits per track.

475 **5.3 Calorimeters**

476 The ATLAS electromagnetic and hadronic calorimeters (EMC and HCAL,
477 respectively) absorb and measure the energy of high energy hadrons, photons,
478 and electrons with $|\eta| < 4.9$. Both systems use sampling calorimeters which
479 consist of alternating layers of dense absorbing and active layers. In the absorbing
480 layer particles interact and lose energy, creating showers. These showers are then
481 detected and measured in the active layer. The amount of charge measured in the
482 active material scales with the energy of the incident particle, and thus provides a
483 measurement of the particle's energy. An overview of the layout of the calorimeter
484 system is shown in Figure 5.6.

485 The EMC measures and contains the energy of electromagnetically interacting
486 particles with 170k channels. It consists of layered accordion-shaped Lead ab-
487 sorber plates and electrodes immersed in liquid Argon. Using accordion-shaped
488 electrode and absorbers ensures ϕ symmetry and coverage. The EMC is com-
489 posed of a barrel part ($|\eta| < 1.475$), two end-caps ($1.375 < |\eta| < 3.2$), and a
490 presampler ($|\eta| < 1.8$). The presampler, containing only liquid Argon, corrects
491 for upstream energy losses of electrons and photons. The EMC barrel is segmented
492 into three layers. The first layer has finest segmentation with readout cells ex-
493 tending $\Delta\eta \times \Delta\phi = 0.025/8 \times 0.1$. This provides a precise shower measurements
494 used to separate prompt photons from $\pi^0 \rightarrow \gamma\gamma$ decays. The second layer has
495 coarser segmentation and is approximately 16 radiation lengths long. A radiation
496 length is the average distance an electron travels before losing all but $1/e$ of its
497 energy to bremsstrahlung. The last layer is the most coarse and measures the tail
498 of the electromagnetic shower. A schematic of the ECAL is shown in Figure 5.7.

499 The hadronic calorimeter located outside the EMC and is used to contain
500 and measure the energy of hadronically interacting particles. It consists of a tile

501 calorimeter (TileCal), hadronic end-cap calorimeter (HEC), and liquid Argon for-
 502 ward calorimeter (FCAL). TileCal is located behind the LAr EMC and uses steel
 503 absorbers and liquid Argon as the active material. TileCal consists of three barrel
 504 layers in the central and forward regions, extending up to $|\eta| < 1.7$. Radiated
 505 photons from the steel tiles are collected via wavelength-shifting fibers connected
 506 to photomultiplier tubes, as shown in Figure 5.8. The HEC lies behind the EMC
 507 endcap wheels. It uses copper absorbers and liquid Argon as the active material
 508 and covers $1.5 < |\eta| < 3.2$. Finally, the FCAL covers $3.1 < |\eta| < 4.9$ and consists
 509 of three modules all using liquid Argon as the active material. The first module
 510 uses copper absorber and was designed for electromagnetic measurements. The
 511 second and third modules consist of tungsten absorber and are used to measure
 512 the kinematics of hadronically interacting particles. A schematic of the HCAL is
 513 shown in Figure 5.8.

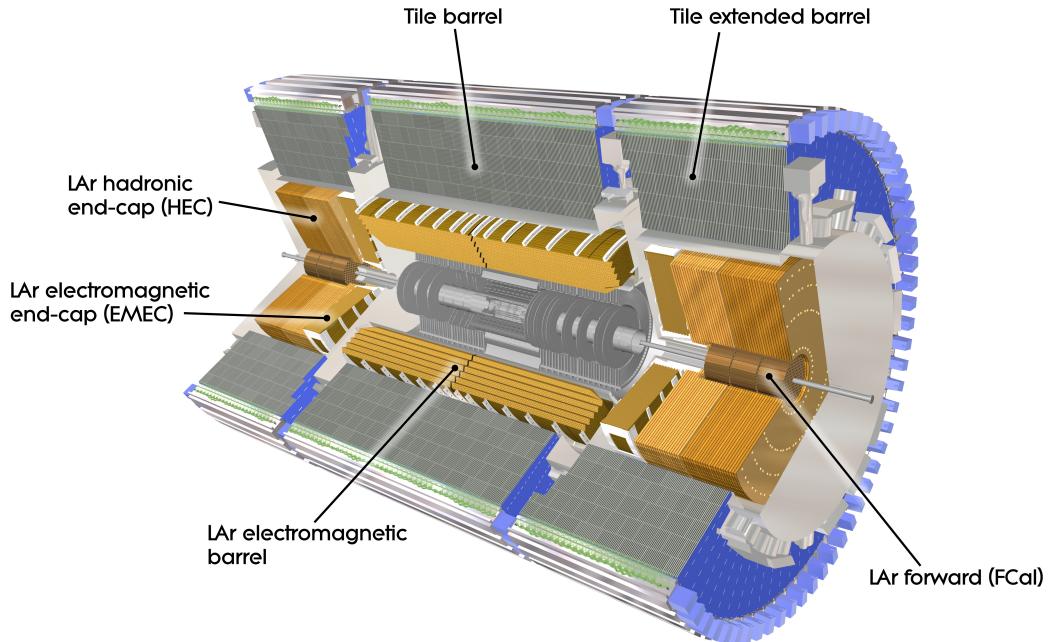

Figure 5.6: Overview of ATLAS electromagnetic and hadronic calorimeters.

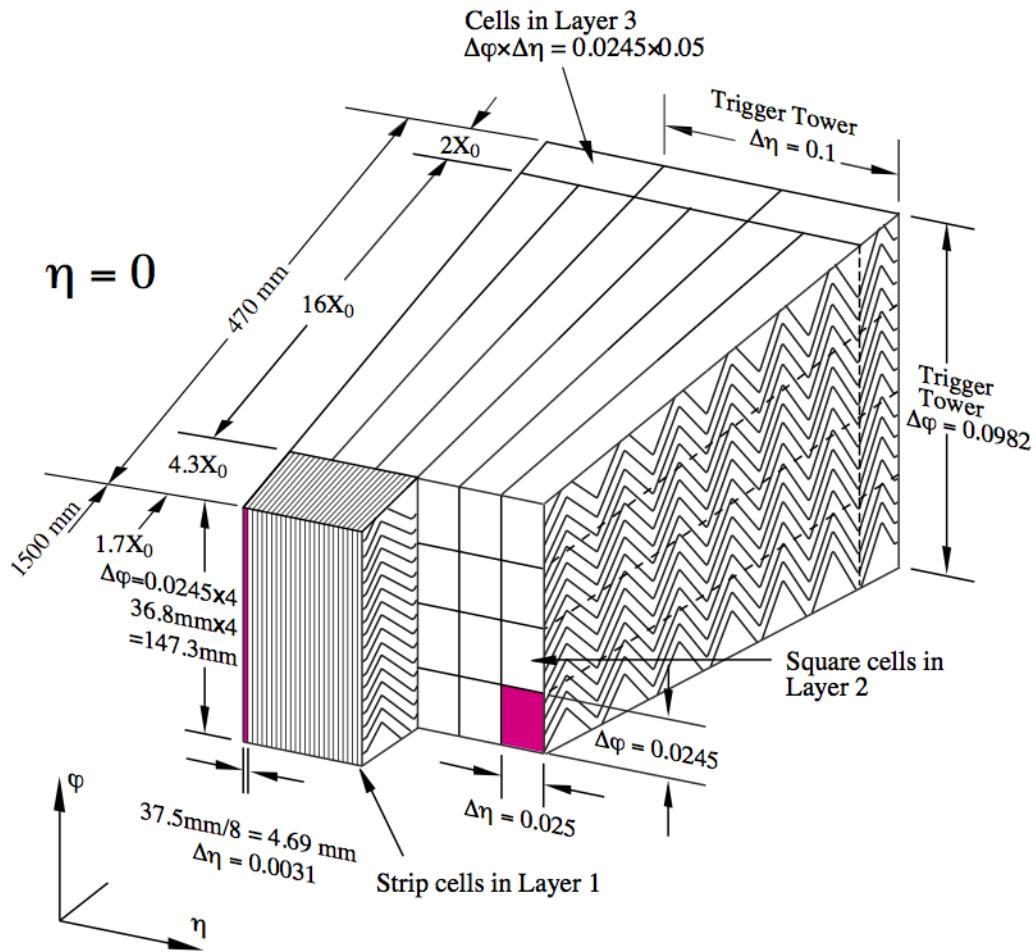

Figure 5.7: Schematic of ECAL.

Figure 5.8: Schematic of HCAL.

514 The energy resolution of the calorimeter subsystems are:

515
$$\frac{\sigma_E}{E} = \frac{10\%}{\sqrt{E}} \oplus 0.7\% \text{ EMC}$$

516
$$\frac{\sigma_E}{E} = \frac{50\%}{\sqrt{E}} \oplus 3\% \text{ hadronic barrel -Natasha check if barrel and end-cap truly}$$

517 have same energy resolution

518
$$\frac{\sigma_E}{E} = \frac{50\%}{\sqrt{E}} \oplus 3\% \text{ hadronic end-cap}$$

519
$$\frac{\sigma_E}{E} = \frac{100\%}{\sqrt{E}} \oplus 10\% \text{ hadronic end-cap}$$

520 5.4 Muon Spectrometer

521 The muon spectrometer (MS) is the outermost detector system in ATLAS.
522 Muons with a $p_T > 4$ GeV are energetic enough to reach the MS. To measure the
523 momentum of these muons two barrel and end-cap toroid magnets are used covering
524 $|\eta| < 1.4$ and $1.6 < |\eta| < 2.7$. For $1.4 < |\eta| < 1.6$, a combination of the barrel
525 and end-cap toroidal magnetic fields bend muon trajectories. The detector in the
526 barrel region form three concentric rings at $R = 5, 7.5, 10$ m and are segmented
527 in ϕ to accommodate the magnets. The end-cap region consists of three circular
528 planes perpendicular to z and located at $|z| = 7.4, 14, 21.5$ m from the interaction
529 region. An additional detector at $|z| = 10.8$ m covers the transition region between
530 the barrel and end-cap.

531 The MS consists of four subsystems: Monitored Drift Tubes (MDT), Cathode
532 Strip Chambers (CSC), Resistive Plate Chambers (RPC), and Thin Gap Cham-
533 bers (TGC). The first two subsystems are used primarily for measuring muon track
534 parameters, while the RPC and TGC subsystems are used for muon triggering.
535 A schematic of this system is shown in Figure 5.9.

536 The MDT subsystem consists of precision tracking chambers for $|\eta| < 2.7$,
537 except for the inner most end-cap layer ($2.0 < |\eta| < 2.7$), where CSCs are used.
538 The basic unit of MDT chambers are thin walled Aluminum tubes with a diameter
539 of 3 cm and length of 0.9-6.2 m. These tubes are filled with a mixture of Ar-CO₂
540 gas with a 50μm W-Rn wires running down the center of the tube which is kept at
541 3080 V. Since the maximum drift time of these chambers is ∼ 700 ns, they are not
542 used for triggering. MDT chambers consist of 3-4 layers of tubes mounted on a
543 rectangular support system, as seen in Figure 5.10, orientated along ϕ to measure
544 the coordinate in the bending plane of the magnetic field with a resolution of 35
545 μm.

546 The MDT subsystem can only handle hit rate below $150\text{Hz}/\text{cm}^2$. For this
547 reason, CSCs are used in the innermost end-cap layer where hit rates are larger.
548 CSCs can handle hit rates up to $1000\text{Hz}/\text{cm}^2$. CSC are multiwire proportional
549 chambers. These chambers are filled with a Ar- CO_2 gas mixture and evenly spaced
550 wires kept at 1900 V. These wires are orientated in the radial direction but not
551 read out. Instead on one side of the cathode are copper strips parallel to the wires,
552 measuring η , while on the other side of the cathode are strips parallel to the wires
553 measuring ϕ . The width between strips is approximately 1.5 mm providing a
554 resolution of $60\ \mu\text{m}$ in the bending-plane and 5 mm in the non-bending plane.

555 Since the CSC and MDT systems do not poor time resolution, the RPC and
556 TGC systems are used for triggering. The RPC system is used in the barrel region
557 ($|\eta| < 1.05$). RPC consist of two parallel resistive plates separated by a 2 mm
558 insulated spacer with 100 mm spacing kept at 9.8 kV 5.11. A gaseous mixture of
559 $\text{C}_2\text{H}_2\text{F}_4$, C_4H_{10} , and SF_6 fills the space between the two plates. Metallic strips
560 on the outer faces of the plates are used to read out signals produced by the
561 gas ionizing. The middle barrel layer consists of two layers of RPCs on either
562 side of the MDT layer and one layer on the outermost MDT layer. Each layer
563 contains two orthogonal sets of metallic strips providing η and ϕ measurements.
564 The timing resolution of RPCs is 1.5 ns, and therefore may be used to identify
565 bunch crossings.

566 Finally, the TGCs are used in the end-cap regions and primarily used to pro-
567 vide L1 trigger decisions and ϕ measurements. TGCs are multi-wire proportional
568 chambers consisting of arrays of gold-coated tungsten wires placed between two
569 cathode planes. These wires are separated by 1.8 mm and cathodes are 1.4 mm
570 from the wires. Orthogonal to the wires, on the opposite side of the cathode plane
571 are copper strips held at 2900 V. The chambers are filled with a mixture of CO_2

572 and n-pentane gas, the latter acts as a quenching gase to prevent avalances initiated
573 by secondary γ -rays from the primary avalanche. Figure 5.12 is a schematic
574 of a TGC. The timing resolution of TGCs is less than 25 ns and therefore are used
575 for bunch crossing measurements.

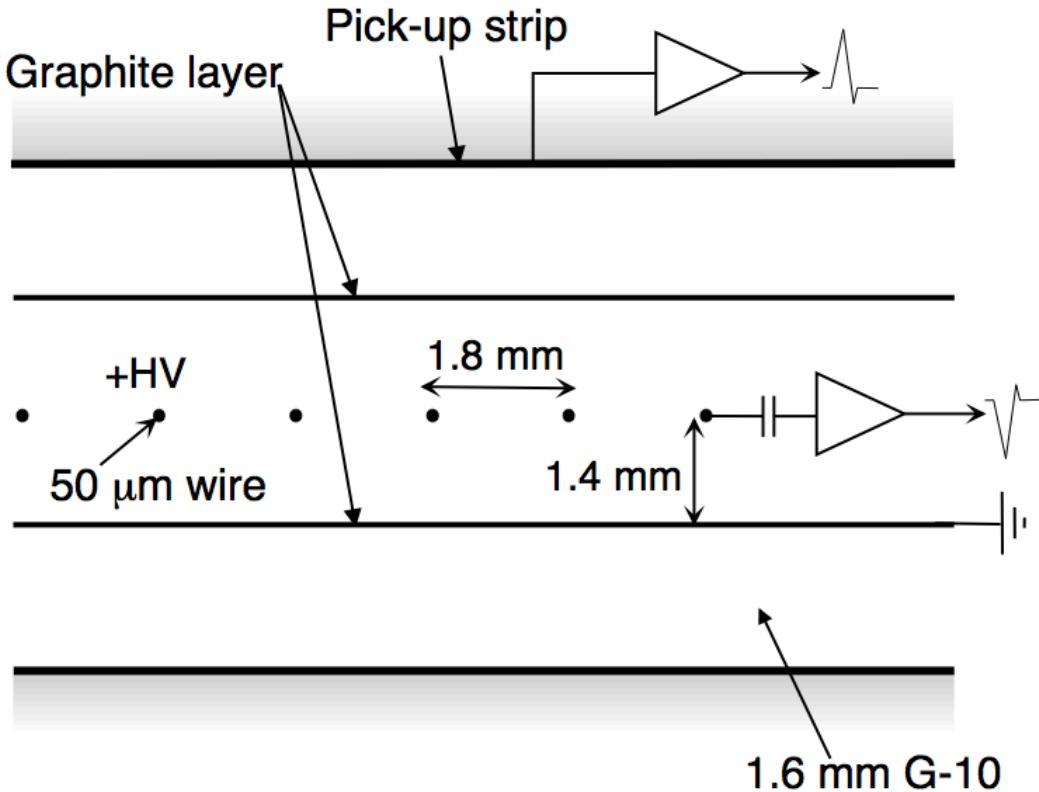

Figure 5.12: Schematic of TGC chamber, which is used for triggering in the muon end-cap region. [cite G35]

576 5.5 Magnet System

577 A particles with charge, q , and velocity v , moving in magnetic field, B , ex-
 578 periences a force, $F = qv \times B$. This force can cause charged particles to have a
 579 curved trajectory in magnetic fields, which the ID and MS use to determine the
 580 particles p_T . The central solenoid provides the magnetic field for the ID and the
 581 toroidal magnets provide the magnetic field for the MS.

582 The layout of the magnet system is shown in Figure 5.13. The central solenoid
 583 consists of a single-layer Al-stabilized NbTi conductor coil wound inside an Al

584 support cylinder. The solenoid is 5.8 m long, 50 cm thick and has an inner radius
585 of 1.23 m. It is cooled to 4.5 K to reach superconducting temperatures and shares
586 the liquid argon calorimeter vacuum vessel to minimize material in the detector.
587 A current of 7.730kA produces a 1.998 T solenoidal magnetic field, pointing in
588 the $+z$ direction.

589 The toroidal magnet system consists of a barrel and two end-cap toroidal
590 magnets used to a magnetic field outside the calorimeters that is orientated along
591 ϕ . Each barrel toroid is 25.3 m long with an inner and outer diameter of 9.4 and
592 20.1 m and weighs 830 tonnes. Endcap toroids are 5 m long with an inner and
593 outer radius of 1.65 and 10.7 m. Both toroid systems use Al-stabilized Nb/Ti/Cu
594 conductors. The magnetic field strength of the barrel and endcap regions are 0.5
595 and 1 T.

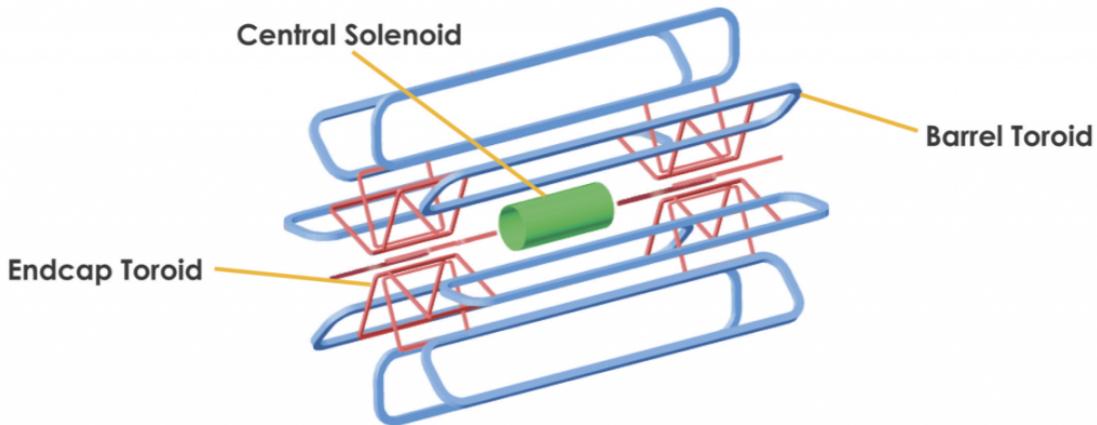

Figure 5.13: Layout of ATLAS magnet systems.

596 5.6 Trigger System

597 Since collisions occur every 25 ns and reading out all detector channels and
598 storing that information is not currently feasible (saving 60 million megabytes per

599 second), the majority of events are not kept for analysis. ATLAS uses a multi-
600 stage trigger system to select approximately 1,000 of the 1.7 billion collisions that
601 occur each second (corresponding to a rate of 1 kHz from the 40 MHz proton
602 collision rate). The first stage of the trigger system is the hardware level (L1)
603 trigger. This trigger reduces the event rate to \sim 100 kHz by identifying Regions-
604 of-Interest (ROIs) containing high p_T leptons, photons, jets, or E_T^{miss} by using
605 information from RPCs, TGCs, and calorimeters to make a $2.5\ \mu s$ decision. This
606 information is then passed to a high-level trigger (HLT) which further decreases
607 event rates to ~ 1 kHz. The HLT uses finer granularity measurements from the
608 MS and ID to perform simplified offline reconstruction to decide which events to
609 keep.

Part III

610

Method

611

612 **Chapter 6**

613 **Dataset and Simulated Samples**

614 **6.1 Dataset**

615 This analysis uses pp collision data collected from 2015 to 2018 at $\sqrt{s} = 13$
616 TeV, corresponding to 139/fb of data as shown in Figure 6.1 and 6.2. From this
617 dataset, only those events in which the tracker, calorimeters, and muon spectrom-
618 eter have good data quality are used. For a given event, the solenoid and toroidal
619 magnets must also be operating at their nominal field strengths. In addition to
620 this, events must pass further quality checks to reject events where detector sub-
621 systems may have failed. These selections reject events that contain LAr noise
622 bursts, saturation in the electromagnetic calorimeter, TileCal errors, and failures
623 in event recovery due to tracker failures. Events with information missing from
624 subsystems (usually due to busy detector conditions) are rejected. Events must
625 also contain a primary vertex with at least two associated tracks, where the pri-
626 mary vertex is selected as the vertex with the largest $\sum p_T^2$ over tracks associated
627 with the vertex and $p_T > 0.5$ GeV.

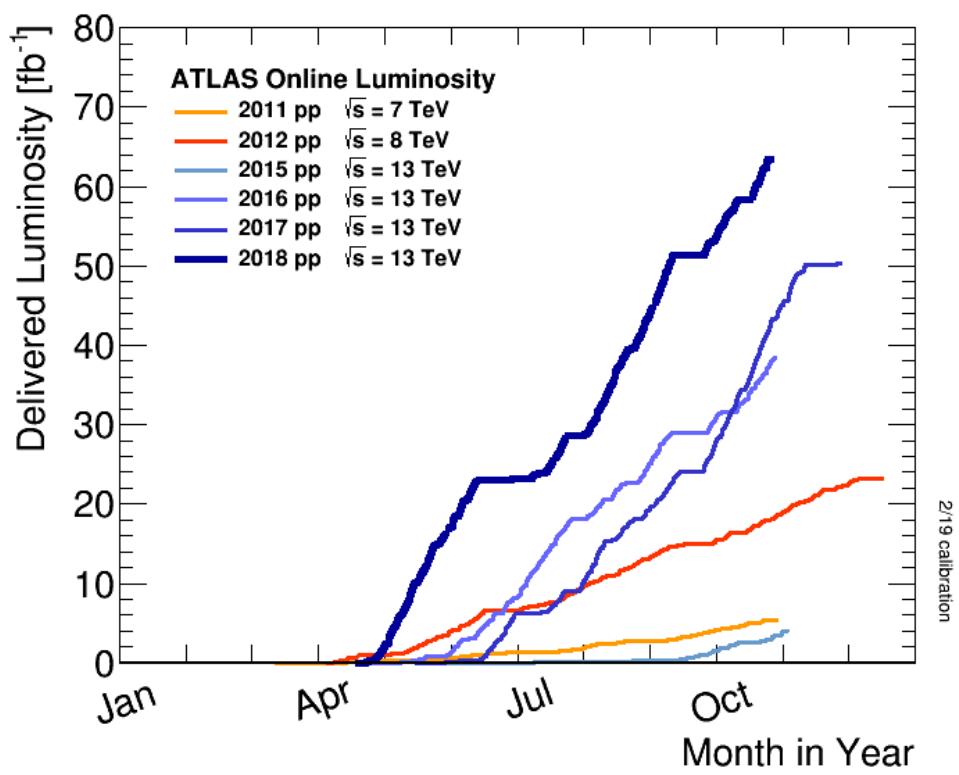

Figure 6.1: Integrated luminosity for data collected from ATLAS from 2011 - 2018

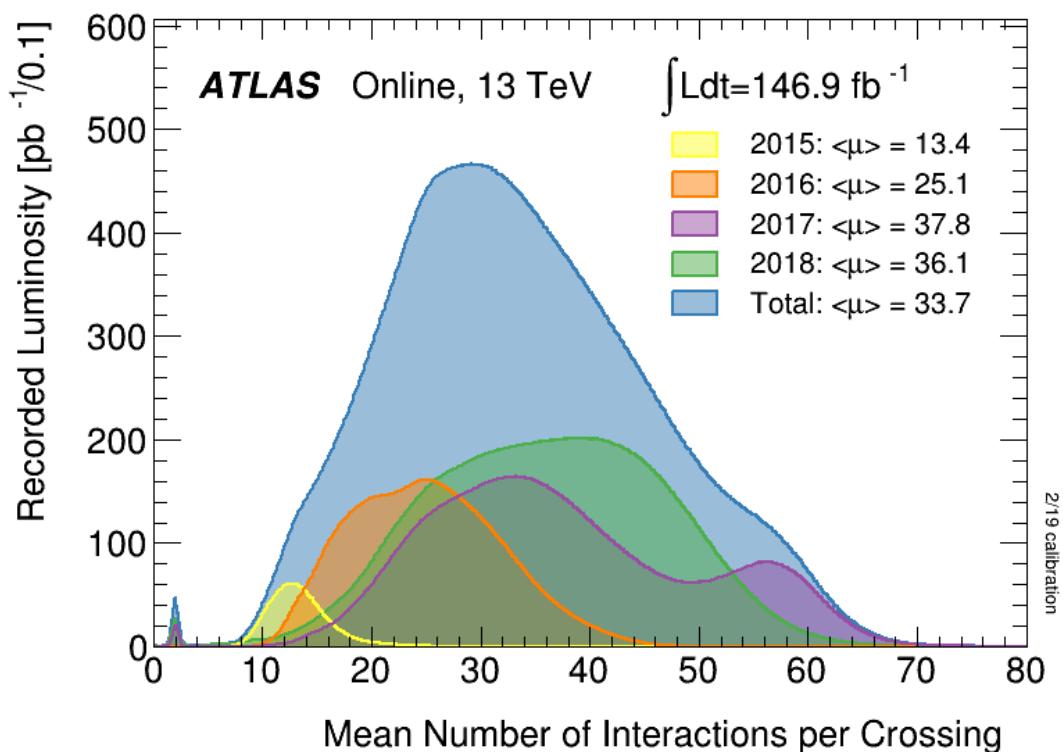

Figure 6.2: Mean number of interactions per crossing for data collected from ATLAS from 2011 - 2018

628 **6.2 Simulated Samples**

629 Samples are simulated in order to model backgrounds, evaluate signal ac-
630 ceptance, optimize event selection and estimate systematic and statistical uncer-
631 tainties. The dominant backgrounds for this analysis are $W/Z + \text{jets}$, diboson
632 (WZ/WW), $t\bar{t}$, single top and multijet production.

633 $W/Z+\text{jet}$ events are simulated using Sherpa 2.2.1 at NLO [cite [29]] and merged
634 with the Sherpa parton shower using the ME+PS@NLO prescription [11]. These
635 events are then normalized to NNLO cross sections. The $t\bar{t}$ and single-top back-
636 grounds are generated with Powheg-Box with NNPDF3.0NLO PDF sets in the
637 matrix element calculation [cite[35]]. For all processes, the parton shower, frag-
638 mentation, and underlying event are simulated using Pythia 8.320 with the A14
639 tune set[cite[ATL-PHYS-PUB-2014-02]]. Diboson processes are generated using
640 Sherpa 2.2.1.

641 Signal samples are simulated using MadGraph 5-2.2.2 [cite 42] and Pythia
642 8.186 with NNPDF230LO. RS Graviton samples are generated with $k/M_{PL}=1$.
643 HVT Model A (B) samples are simulated with $g_V = 1(3)$, as the difference in the
644 width of the samples is smaller than detector resolution. Model C is generated by
645 setting $g_H = 1$ and $g_f = 0$ to model VBF production of HVT bosons. Signals are
646 generated for masses between 300 GeV and 6 TeV.

647 **6.3 Object Selection**

648 **6.3.1 Electrons**

649 Electrons are reconstructed from electromagnetic showers in the LAr EM
650 calorimeter. During reconstruction cells of $\Delta\eta \times \Delta\phi = 0.025 \times 0.025$ are grouped
651 into 3×5 clusters. These clusters are then scanned for local maxima that seed

652 electron clusters. These clusters must then be matched to ID track from the PV.
653 This requirement minimizes non-prompt electron and fake electron backgrounds.
654 Electrons must pass identification and isolation requirements. Electron identifica-
655 tion (loose, medium, tight) classification is based on a multivariate discriminant
656 that identifies electrons using a likelihood based method. For this analysis tight
657 electrons are used. Electrons are also required to be isolated. The electrons are
658 considered isolated if the quotient of the sum of the transverse momentum (of
659 calorimeter energy deposits) in a cone around the electron of size $\Delta R = 0.2$ and
660 the transverse momentum of the electron to be less than $0.015 * p_T$ or 3.5 GeV,
661 whichever is smaller. This requirement rejects non-prompt photons and other
662 fake leptons. Electrons in this analysis are also required to have $p_T > 30$ GeV and
663 $|\eta| < 2.47$. Electrons are also required to have $p_T > 30$ GeV.

664 Electrons are calibrated to determine data-driven scale factors from $J/\Psi \rightarrow ee$,
665 $Z \rightarrow ee$, $Z \rightarrow \ell\ell\gamma$ processes. These corrections account for the non-uniform
666 response of the detector by introducing modeling and reconstruction uncertainties.

667 6.3.2 Muons

668 As muons traverse the entire detector, they are reconstructed from ID and MS
669 tracks. For this analysis the muon identification and isolation working points are
670 chosen to minimize the contributions from non-prompt muons. Towards this end,
671 the medium muon identification working point is used. For this working point,
672 two types of reconstructed muons are used: combined and extrapolated muons
673 (CB and ME, respectively). For CB muons, ID and MS tracks are reconstructed
674 independently and a combined track fit is performed by adding or removing MS
675 tracks to improve the fit quality. ME muons are reconstructed from only MS
676 tracks with hits in at least two layers, which ensures the track originates from the

677 PV. ME muons extend the acceptance for muon reconstruction outside the ID
678 from $2.5 < |\eta| < 2.7$. The medium identification working point uses CB and ME
679 tracks. CB tracks must have at least 3 hits in two MDT layers. ME tracks are
680 required to have at least three MDT/CSC hits. To further minimize contributions
681 from fake muons, the selected muons are required to be isolated from other tracks,
682 as muons from W, Z decays are often isolated from other particles. To insure the
683 selected muons are isolated, the scalar sum of the transverse momentum of tracks
684 in a cone of $\Delta R = 0.3$ compared to the transverse momentum of the muon must
685 be less then 0.06. Muons are also required to have $p_T > 30$ GeV.

686 Muons are calibrated using well-studied resonances $J/\Psi \rightarrow \mu\mu$ (low- p_T), $Z \rightarrow$
687 $\mu\mu$ (high- p_T). Figure 6.3 shows the combined muon p_T uncertainty from this
688 calibration. The total systematic uncertainty is less then 1% for all p_T ranges
689 considered in this analysis.

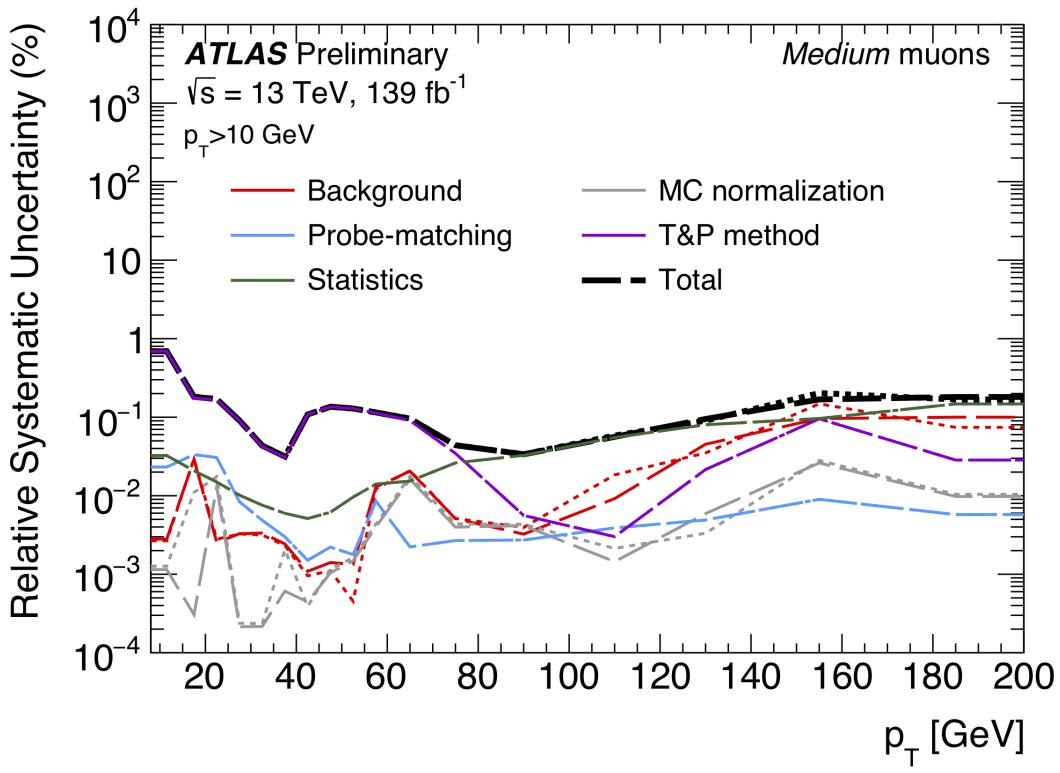

Figure 6.3: This figure shows the breakdown of the muon reconstruction efficiency scale factor measured in $Z \rightarrow \mu\mu$ as a function of p_T [4].

6.3.3 small-R jets

Small-R jets are used to reconstruct the hadronically decaying W/Z candidates in the resolved analysis and VBF jets. These jets are less boosted and therefore spatially separated and reconstructed separately. These jets are constructed from topologically connected clusters of calorimeter cells (topoclusters), seeded from calorimeter cells with energy deposits significantly above the noise threshold. These cells are then used as inputs to the $anti-k_t$ algorithm [12] with a distance = 0.4, here called small-R jets. These jets are calibrated to compensate and account for biases from jet reconstruction.

The jet energy is calibrated sequentially as shown in Figure 6.4. After the jet

700 direction is corrected to point to the PV, the energy of the jet is corrected. First,
701 the jet energy is corrected to account for pileup contributions based on the p_T and
702 area of the jet (these corrections are extracted from a $pp \rightarrow jj$ sample). Following
703 this, another pileup correction is applied that scales with μ and N_{PV} .

704 Then, MC-based corrections are applied that are meant to transform the jet
705 energy and η back to truth level. Therefore, these corrections account for the
706 non-compensating nature of the ATLAS calorimeters and inhomogeneity of the
707 detector. Following this the Global Sequential Calibration is applied that reduces
708 flavor dependence and jet that deposit energy outside the calorimeters. Finally,
709 in-situ corrections are applied that account for differences in jet responses between
710 data and simulation ($\gamma/Z+jet$ and multijet samples are used). These differences
711 can be due to mismodelling of the hard scatter event, pile-up, jet formation, etc.

712 Jet used in this analysis must have $p_T > 30$ GeV and $|\eta| < 2.5$. To further
713 reduce fake jets the jet-vertex-tagger (JVT) is used to reject pile-up jets [cite 43
714 P]. The JVT uses two track-based variables, corrJVF and R_{p_T} to calculate the
715 likelihood that the jet originated from the PV. The corrJVF compares the scalar
716 sum of the p_T of tracks associated with the jet and PV to the scalar sum of the
717 p_T of tracks associated with the jet. This variable also includes a correction that
718 reduces the dependency of corrJVF with the number of reconstructed vertices in
719 the event. The other discriminant, R_{p_T} , is given by the ratio of the scalar sum
720 of the p_T of tracks associated with the jet and PV to the p_T of the jet. Both of
721 these variables peak around zero for pileup jets, as these jets are unlikely to have
722 tracks associated with the PV. JVT cuts are applied to all jets with $p_T > 120$
723 GeV. Central jets ($|\eta| < 2.4$) are required to have a $JVT > 0.59$ and forward jets
724 ($2.4 < |\eta| < 2.5$) are required to have $JVT > 0.11$.

725 To further reject fake jets, jets must pass quality requirements based on the

726 following variables ([cite P42]):

727 - f_Q^{LAr} : fraction of energy of jet's LAr cells with poor signal shape

728 - f_Q^{HEC} : fraction of energy of jet's HEC cells with poor signal shape

729 - E_{neg} : sum of cells with negative energy

730 - f_{EM} : fraction of jet's energy deposited in EM calorimeter

731 - f_{HEC} : fraction of jet's energy deposited in HEC calorimeter

732 - f_{max} : maximum energy fraction in any single calorimeter layer

733 - f_{ch} : ratio of the scalar sum of the p_T of a jet's charged tracks to the jet's p_T

734 Jets selected for the resolved analysis must pass one of the following criteria:

735 - $f_{HEC} > 0.5$ and $|f_Q^{HEC}| > 0.5$ and $\langle Q \rangle > 0.8$

736 - $|E_{neg}| > 60$ GeV

737 - $f_{EM} > 0.95$ and $f_Q^{LAr} > 0.8$ and $\langle Q \rangle > 0.8$ and $|\eta| < 2.8$

738 - $f_{max} > 0.99$ and $|\eta| < 2$

739 - $f_{EM} < 0.05$ and $f_{ch} < 0.05$ and $|\eta| < 2$

740 - $f_{EM} < 0.05$ and $|\eta| > 2$

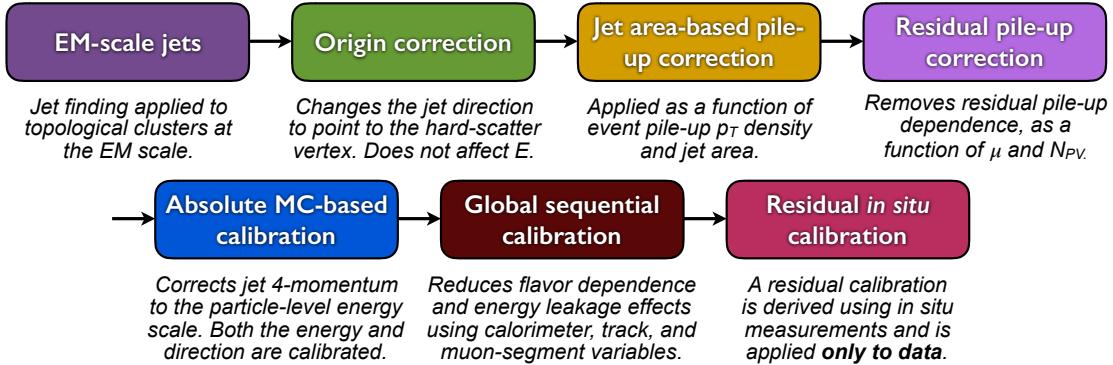

Figure 6.4: [6] This diagram shows the calibration stages for EM jets.

741 6.3.4 large-R jets

742 Large-R ($\Delta R = 1.0$) jets are used to reconstruct the high- $p_T W/Z \rightarrow qq$ candi-
 743 dates in the merged analysis. Track-Calorimeter Clusters (TCCs) are used to reconstruct
 744 these jets [cite ANA 50]. These jets are constructed via a pseudo particle flow
 745 method using ID tracks matched to calorimeter clusters. The angular resolution
 746 of the calorimeter degrades sharply with jet p_T , but the jet energy resolution im-
 747 proves. The tracker has excellent angular resolution improves with p_T . Therefore,
 748 by matching tracks to jets, TCCs have more precise energy and angular resolution
 749 the jets constructed from calorimeter information only. These jets are required to
 750 have $p_T > 200$ GeV, $|\eta| < 2.0$ and $m_J > 50$ GeV.

751 TCC jets are trimmed as detailed in [cite ANA 45], which suppresses pileup
 752 and soft radiation in the jet, the jet mass is calculated as the four-vector sum
 753 of the jet's constituents (assuming massless constituents). The jet mass peaks
 754 around the W/Z boson mass for $W/Z \rightarrow qq$ jets, and more broadly for quark and
 755 gluon induced jets.

756 These jets are then tagged as W/Z jets if they pass the jet mass and D_2
 757 cuts. The jet substructure variable D_2 is given by the ratio of energy correlation
 758 functions based on energies and pair-wise angles of a jet's constituents [cite ANA

759 46, 47]:

$$D_2^{\beta=1} = E_{CF3} \left(\frac{E_{CF1}}{E_{CF2}} \right)^3 \quad (6.1)$$

760 Where the energy correlation functions are defined as:

$$E_{CF1} = \sum_i p_{T,i} \quad (6.2)$$

761

$$E_{CF2} = \sum_{ij} p_{T,i} p_{T,j} \Delta R_{ij} \quad (6.3)$$

762

$$E_{CF3} = \sum_{ijk} p_{T,i} p_{T,j} p_{T,k} \Delta R_{ij} \Delta R_{jk} \Delta R_{ki} \quad (6.4)$$

763 A two-dimensional optimization of the jet mass and D_2 thresholds was per-
764 formed to provide maximum sensitivity for this analysis. Figure 6.5 shows the
765 optimized thresholds on D_2 and jet mass as a function of p_T . Figure 6.6 shows
766 the efficiency of the optimized W/Z taggers as a function of jet p_T .

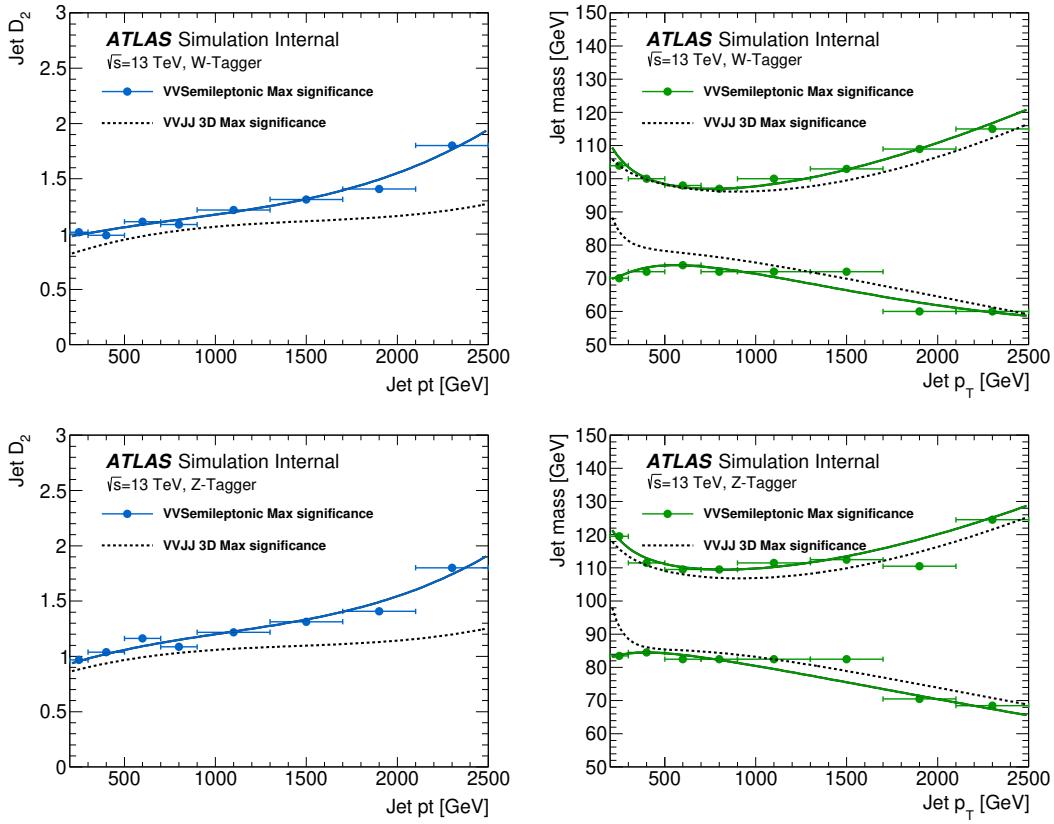

Figure 6.5: The upper cut on D_2 (a) and jet mass window cut i.e. the upper and lower boundary of the mass (b) of the W -tagger as a function of jet p_T . Corresponding values for Z -tagger are shown in (c) and (d). The optimal cut values for maximum significance are shown as solid markers and the fitted function as solid lines. Working points from $VV \rightarrow JJ$ [ATLAS-HDBS-2018-31-002] is also shown as dashed lines as a reference. Natasha reword?

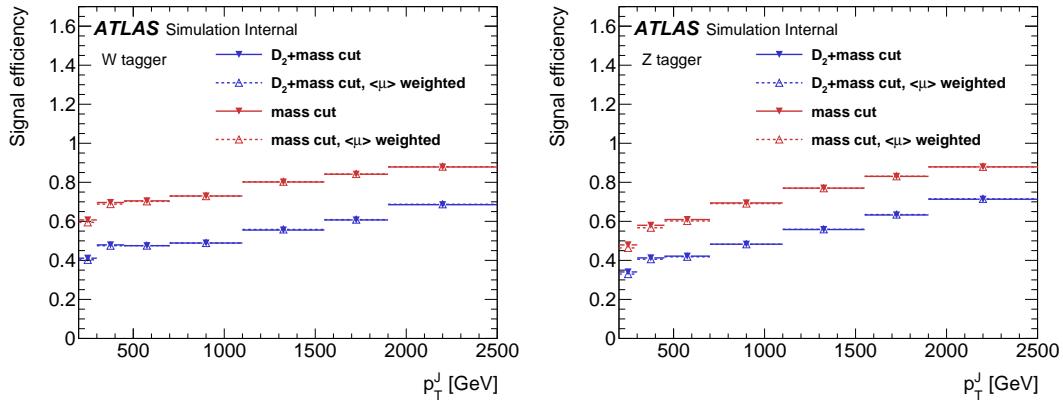

Figure 6.6: Natasha write caption

767 **6.3.5 Variable Radius jets**

768 Variable-radius (VR) track jets are used to identify b-quark induced jets within
769 the catchment area of large-R jets [cite ANA 52]. These jets use a p_T dependent
770 cone size defined as:

$$R_{eff}(p_{T,i}) = \frac{\rho}{p_{T,i}} \quad (6.5)$$

771 for building jets from ID tracks with an anti- k_t algorithm. For this analysis $\rho = 30$
772 GeV and an upper and lower limit on cone size are set to 0.02 and 0.4, respectively.
773 Collinear VR jets are possible, so track jets that are not separated by the the
774 smaller jet's cone size are not used. These jets are also required to have $p_T > 10$
775 GeV and $|\eta| < 2.5$.

776 **6.3.6 MET/neutrinos**

777 As neutrinos are uncharged and colorless they do not leave tracks or jets in the
778 detector. For this reason, neutrinos are reconstructed calculated the E_T^{miss} , the
779 negative vector sum of p_T all the physics objects and an extra "soft" term. The
780 "soft" term accounts for energy deposits not associated with any of the objects in
781 the event. For this analysis the soft term is given by the sum p_T of all ID tracks
782 not associated with objects in the event. The selected tracks must be matched to
783 the primary vertex, which decreases pile-up contamination [cite G 217 218]. The
784 tight working point is used [Natasha look up what this means].

785 **6.3.7 Jet Flavor Tagging**

786 To further classify events, the small radius jets originating from a b-quark are
787 classified using a multivariate b -tagging algorithm (BDT), MC2c10 [cite G 210
788 199]. This algorithm uses the impact parameters of the jet's ID tracks, secondary

789 vertices (if they exist), and reconstructed flight paths of b and c hadrons in the jet
790 to determine if the jet was induced by a b -quark. For this analysis the 85% efficient
791 working point of this algorithm is used to a fixed cut on the BDT discriminant
792 that yields an 85% tag rate, and c , τ , and light-flavor jet rejection of 3, 8, and 34
793 respectively in a simulated $t\bar{t}$.

794 **6.3.8 Overlap Removal**

795 Reconstructed jets and leptons in this analysis can arise from the same energy
796 deposits. For instance, a cluster of energy from an electron can also be a valid
797 calorimeter seed for a jet. To mitigate this confusion of multiple objects originating
798 from a single jet or lepton overlapping objects are removed via a procedure referred
799 to as overlap removal. In this procedure the separation of the two objects, $\Delta(R) =$
800 $\sqrt{(\Delta\eta)^2 + (\Delta\phi)^2}$ determines which object is removed from the event.

801 The overlap selections used in this analysis are:

- 802 - when an electron shares a track with another electron with the lower p_T
803 electron is rejected, as it is more likely to be a fake electron
- 804 - when a muon and electron share a track the muon is rejected if it is a
805 calo-muon, otherwise the electron is rejected
- 806 - when $\Delta R < 0.2$ for an electron and jet, the jet is rejected to maximize signal
807 acceptance
- 808 - when $\Delta R > 0.2$ for an electron and jet, the electron is rejected as likely
809 originated from decays within the jet
- 810 - when $\Delta R < \min(0.4, 0.04 + 10\text{GeV}/p_T^\mu)$ the muon is rejected, again maximiz-
811 ing signal acceptance, otherwise the jet is rejected

₈₁₂

- when $\Delta R < 1.0$ for the a large-R jet and electron, the jet is rejected

813 **Chapter 7**

814 **Event Selection and**

815 **Categorization**

816 **7.1 Pre-selection**

817 Before applying topological cuts to suppress backgrounds and reduce data
818 size in this search, preselection cuts are applied which include trigger and event
819 requirements. Events must contain exactly one tight lepton (no additional loose
820 leptons), the $p_T^{\ell\nu} > 75$ GeV, and there must be at least two small-R jets or one
821 large-R jet.

822 **7.2 Trigger**

823 The data were collected using the lowest unprescaled single-lepton or E_T^{miss}
824 triggers, as summarized in Table ???. Since the muon term is not considered in the
825 trigger E_T^{miss} calculation, the E_T^{miss} trigger is fully efficient to events with high- p_T
826 muons. For this reason, the E_T^{miss} trigger is used for events where $p_T^\mu > 150$ GeV, to
827 compensate for the poor efficiency of the single muon trigger above $p_T^\mu > 150$ GeV.

Table 7.1: The list of triggers used in the analysis.

Data-taking period	$e\nu qq$ channel	$\mu\nu qq$ ($p_T(\mu\nu) < 150$ GeV) channel	$\mu\nu qq$ ($p_T(\mu\nu) > 150$ GeV) channel

828 **7.3 GGF/VBF RNN**

829 To classify events as originating from GGF/DY or VBF production a recursive
830 neural network (RNN [17]) is used. This approach is more powerful than a cut-
831 based classification as it improves signal efficiency and analysis sensitivity by
832 exploiting correlations between variables that the RNN learns. In particular, a
833 RNN architecture is ideal as it can handle variable numbers of jets in the events.

834 The RNN uses the four-momentum of candidate VBF jets to classify events
835 as VBF or GGF topologies. As sometimes jets will be incorrectly reconstructed
836 the number of jets in the event are expected to vary across the inputs samples.
837 VBF candidate jets are identified by removing jets from the event that are likely
838 from $W/Z \rightarrow qq$. For the resolved regime this means removing the two leading
839 small-R jets from the VBF candidate jet list. For the merged regime this means
840 removing small-R jets separated by less than 1.0 in dR from the large-R jet. VBF
841 candidate jets are also required to be within $|\eta| < 4.5$. From the list of remaining
842 VBF candidate jets, the two highest- p_T jets are chosen.

843 The architecture of the RNN is show in Figure 7.1. LSTMs are a type of
844 RNN that extract meaningful information and can retain it (unlike other neural
845 networks architectures). This is useful for VBF event classification for events with
846 two jets, where using the kinematic properties of both jets (and their correlations)
847 will lead to more efficient event classification.

848 In this RNN architecture, the VBF candidates are first passed to a masking
849 layer which checks the number of jets in the event. If there is only one jet, only one
850 LSTM layer is used. The output of masking is then passed to a Long Short-Term
851 Memory (LSTM) cell, with a tanh activation function. This output is passed to
852 a dropout layer, that has a probability of 0.3 to completely forget the output of
853 the LSTM. Dropout is a regularization method, that prevents over-fitting. The

854 output of the dropout layer is then passed to the second LSTM and then through
855 another dropout layer with a probability of 0.3.

856 The weights and other parameters of the network are learned by training the
857 network with VBF and GGF signals over 200 epochs with an Adam Optimizer
858 [natasha add reference]. The training is truncated if the network parameters are
859 unchanged after ten iterations. The training, testing and validation sets are 56,
860 30, and 14 percent of the input samples, respectively. Figure [add INT figure
861 32] shows the loss function of the network as a function of training epochs. The
862 validation test set has a smaller loss function as dropout was not applied. Figure
863 7.3 shows the ROC curve for the RNN using k-fold cross validation.

864 Finally this output is passed to a dense layer [natasha ask antonio about this]
865 and then to a sigmoid activation layer, leading to an overall RNN score. Figure
866 7.2 shows the RNN discriminant for backgrounds, GGF signals, and VBF signals.
867 The RNN score is ~ 0 for GGF and background processes and ~ 1 for VBF
868 processes. Figure 7.4 shows the limits for various signal processes based on the
869 RNN cut applied. The most efficient cut was found to be RNN Score > 0.8 , for
870 VBF classification.

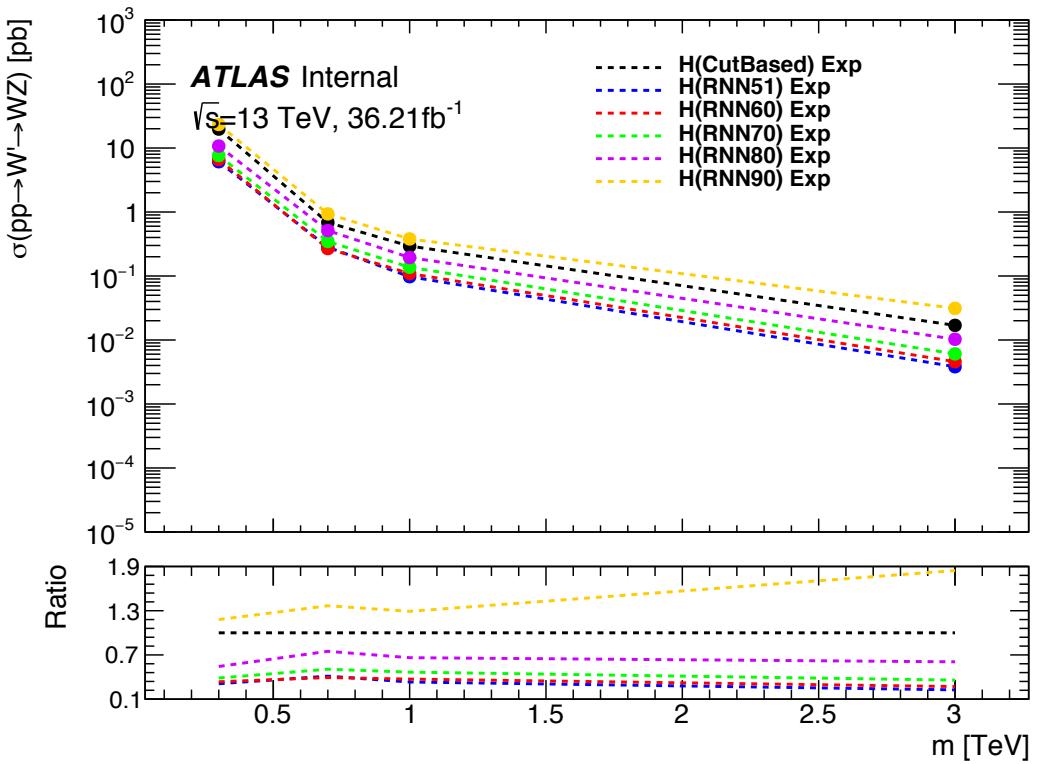

Figure 7.4: Comparison of GGF Z' limits for different RNN score selections.

871 7.4 Topological Cuts

872 Once an event is classified as VBF or GGF via the RNN it must pass other
 873 topological cuts that maximize signal efficiency and background rejection. First,
 874 to efficiently select events with $W \rightarrow \ell\nu$ candidate exactly one tight lepton is
 875 required and $E_T^{miss} > 100(60)$ GeV and $p_{T,\ell\nu} > 200(75)$ GeV in the merged (re-
 876 solved) analysis to suppress the multi-jet background. To more accurately model
 877 the two dominant backgrounds in this analysis, $W + \text{jets}$ and $t\bar{t}$, control regions are
 878 used constructed for each. These control regions are dominated by these processes
 879 and used to extract normalization factors that are then used in the signal region
 880 estimates.

881 For the merged analysis, in addition to the $W \rightarrow \ell\nu$ and $W/Z \rightarrow J$ selections

above, the relative boson p_T is cut to enhance signals, i.e. $\min(p_{T,\ell\nu}, p_{T,J})/m_{WV} > 0.35(0.25)$ for the GGF (VBF) category. To minimize $t\bar{t}$ contamination the signal region and $W+\text{jets}$ control region events with at least one b jet with $\Delta R > 1.0$ from the large-R jet are excluded. For the $t\bar{t}$ control region the event must contain at least one such b jet. High purity signal regions require the D_2 and W/Z mass window cut to be passed, whereas the low purity region only requires the W/Z mass window cut to be passed. Finally for events to be classified as tagged the large-R jet must contain exactly two b-tagged jets. Untagged events must have no more than one b-tagged jet matched to the large-R jet. These selections are shown in Table 7.2. The distributions for the variables used in merged analysis for top control regions are shown in Figure 7.6-7.9.

Events failing the merged selection are then re-analyzed in the resolved category. To enhance resolved signals, the event should contain two high- p_T boson that are back-to-back in the x-y plane as shown by the cuts in Table 18. Again to suppress the $t\bar{t}$ background in the WCR and SR events are required to have no additional b-jets.

The WV system mass, m_{WV} is reconstructed from the lepton, neutrino, and hadronically-decaying boson candidate. The momentum of the neutrino along the z -direction is obtained by constraining the $W((Z))$ boson mass of the lepton neutrino system to be 80.3 (91.8) GeV/c^2 . For complex solutions to this constraint, p_Z is taken as either the real component of the complex solutions or the one with the smaller absolute value of the two real solutions. For the resolved analysis, m_{WV} is reconstructed by constraining the $W(Z)$ dijet system:

$$p_{T,jj}^{corr} = p_{T,jj} \times \frac{m_{W/Z}}{m_{jj}} \quad (7.1)$$

$$m_{jj}^{corr} = m_{W/Z} \quad (7.2)$$

Table 7.2: Summary of selection criteria used to define the signal region (SR), W +jets control region (W CR) and $t\bar{t}$ control region ($t\bar{t}$ CR) for merged 1-lepton channel.

Selection	SR		W CR (WR)		$t\bar{t}$ CR (TR1)			
	HP	LP	HP	LP	HP	LP		
$W \rightarrow \ell\nu$	Num of Tight leptons			1				
	Num of Loose leptons			0				
	E_T^{miss}			> 100 GeV				
	$p_T(\ell\nu)$			> 200 GeV				
$W/Z \rightarrow J$	Num of large- R jets			≥ 1				
	D_2 cut	pass	fail	pass	fail	pass	fail	
	W/Z mass window cut	pass	pass	fail	fail	pass	pass	
	Numb. of associated VR track jets b -tagged	For $Z \rightarrow J$: ≤ 1 ($= 2$) for untagged (tagged) category						
	$\min(p_{T,\ell\nu}, p_{T,J}) / m_{WZ}$	> 0.35(0.25) for DY/ggF (VBF) category						
	Top-quark veto	Num of b -tagged jets outside of large- R jet	0		≥ 1			
Pass VBF selection			no (yes) for DY/ggF (VBF) category					

906 where m_{jj} and $m_{W/Z}$ are the reconstructed invariant mass of the hadronically-
907 decaying W/Z boson and the PDG values of the W/Z boson masses, respectively.
908 A summary of the resolved selections is shown in Table 7.3. The distributions for
909 the variables used in the resolved analysis in the TCR are shown in Figure 7.10,
910 7.11.

911 Events classified as VBF events are classified as Merged High purity, low
912 purity or resolved signal region selections sequentially. If the event does not pass
913 any of these selections but passes a VBF control region selection it is classified as
914 a VBF CR event. If the event fails the VBF selection it is then checked if it passes
915 the Merged High purity, Low purity or resolved signal region selections (NB: for
916 the WZ decay modes all the regions have tagged and untagged categories). If the
917 event fails all the GGF signal region selections, it is then kept for GGF control
918 region selections, if it passes those selections. This cutflow is shows in Figure 7.5.

Table 7.3: The list of selection cuts in the resolved analysis for the WW and WZ signal regions (SR), $W+\text{jets}$ control region (WR) and $t\bar{t}$ control region (TR).

cuts	SR	W CR (WR)	$t\bar{t}$ CR (TR1)
$W \rightarrow \ell\nu$	Number of Tight leptons	1	
	Number of Loose leptons	0	
	E_T^{miss}	$> 60 \text{ GeV}$	
	$\cancel{p}_T(\ell\nu)$	$> 75 \text{ GeV}$	
$W/Z \rightarrow jj$	Number of small-R jets	≥ 2	
	Leading jet p_T	$> 60 \text{ GeV}$

919 **7.5 Selection Acceptance times efficiency for Sig-**
 920 **nal Events**

921 The acceptance times efficiency for the signal region selection is defined as:

$$A \cdot \epsilon = \frac{N_{\text{events selected}}^{\text{truth}}}{N_{\text{events generated}}^{\text{truth}}} \cdot \frac{N_{\text{events selected}}^{\text{reco}}}{N_{\text{events selected}}^{\text{truth}}} = \frac{N_{\text{events selected}}^{\text{reco}}}{N_{\text{events generated}}^{\text{truth}}} \quad (7.3)$$

922 The distributions of $A \cdot \epsilon$ as a function of the resonance mass for the different spin
 923 models are shown in Figures 7.13 - ??.

924 7.6 Background Estimate

925 7.6.1 Multijet Sample

926 Backgrounds in this analysis containing real leptons (e.g. $W/Z + \text{jets}$, diboson,
 927 $t\bar{t}$, single- t) are well-modeled with simulated samples and constrained with data
 928 from CRs. However, the multijet background containing fake leptons is not well-
 929 modeled with simulation. For this reason, the multijet background is extracted
 930 from data. Heavy flavor decay products, jets, and converted photons can be
 931 mistakenly reconstructed as jets. Fake electrons often arise from jet fakes while
 932 fake muons may also arise from heavy flavor decay. For this analysis, these fake
 933 electrons generally fail the electron ID criteria and fake muons fail the muon
 934 isolation requirement. Therefore, to derive the multijet template shape the SR
 935 and CR selections and inverted lepton requirements are used as seen in Table
 936 7.4. NB: by inverting the lepton isolation/identification criteria the CR and SRs
 937 created are orthogonal to the CR and SRs.

938 The template shape of the MJ background is determined by using a multijet
 939 validation region (MJVR) that requires the inverted lepton isolation/id require-

940 ment and the two signal jets to satisfy the m_{jj} requirement used in the $W+jets$
941 CRs. The E_T^{miss} distribution in MJCR is shown in Figure 7.14 for 2017 data.
942 The template is then extracted by subtracting the data in the MJVR from the
943 electroweak background processes. This template is then added in the WCR
944 and a "pre-MJ-fit" is preformed. In this fit the E_T^{miss} distribution is fit with the
945 electroweak background normalizations constrained to expected ranges and the
946 multijet electron and muon background normalizations free to float. The fitted
947 scale factors from this MJVR template are then applied in the MJCR template.
948 The fitted uncertainties on the MJCR normalizations are then used to create the
949 MJ template in the SRs. The electron and muon background normalizations are
950 parameters in the final simulateous fit. Technically, there should be a separate
951 template for every CR and SR, but some MJ regions have insufficient statistics to
952 do this. Additionally, the shapes for the MJ templates for VBF and ggF regions
953 are found to be compatible within statistical uncertainty. Therefore, the sample
954 MJ template used for VBF and ggF CR/SRs, but with different pre-MJ-fit scale
955 factors.

956 This template method was validated using WCR and full Run 2 data. The
957 results of the fit are shown in Table 7.5. The multijet contribution in the muon
958 channel for $p_T^W > 150$ GeV is consistent with zero, and therefore neglected in
959 the final fit. Applying the extracted normalization factor to MJVR in WCRs for
960 various kinematic variables such as E_T^{miss} , W transverse mass, lepton p_T , and the
961 invariant mass as show in Figures 7.15 -7.24. These figures show good agreement
962 between the data and background estimate.

Table 7.5: Fit validation result in WCRs for 2015+16 data. The fit is done in various WCRs, in order to obtain the corresponding scale factors for MJ templates: ggF resolved WCR for the $WW \rightarrow lvqq$ selection, ggF resolved untagged WCR for the $WZ \rightarrow lvqq$ selection, ggF resolved tagged WCR for the $WZ \rightarrow lvqq$ selection, VBF resolved WCR for the $WW \rightarrow lvqq$ selection, and VBF resolved WCR for the $WZ \rightarrow lvqq$ selection. Post-fit event yields for electroweak processes and MJ contributions are shown. The SF column shows the corresponding normalization scale factors for electroweak processes from the fit. R.U. stands for relative uncertainty.

964 **Chapter 8**

965 **Systematic Uncertainties**

966 This section describes the sources of systematic uncertainties considered in
967 this analysis. These uncertainties are divided into three categories: experimental
968 uncertainties, background modeling uncertainties, and theoretical uncertainties on
969 signal processes. In the statistical analysis each systematic uncertainty is treated
970 as a nuisance parameter estimated on the m_{VV} distribution.

971 **8.1 Experimental Systematics**

972 The uncertainty on the integrated luminosity of the dataset used is 1.7% and
973 a systematic in the final fit. The luminosity uncertainty is calculated following a
974 methodology similar to the one in [ref P55].

975 Also, multiple pile up interactions are simulated to match data conditions.
976 This ensures simulated detector response and particle reconstruction conditions
977 are as similar as possible. The distribution of the average number of interactions
978 per bunch crossing applied to simulation is called the μ profile. The pileup mod-
979 eling uncertainty is accounted for by re-weighting simulated events so the average
980 number of interactions per bunch crossing varies within its uncertainty due to

981 systematics from vertex reconstruction [ref ATL-COM-SOFT-2015-119]. The as-
982 sociated re-weighting factors are propagated through the entire analysis chain to
983 construct a systematic uncertainty on m_{VV} .

984 The single-lepton and E_T^{miss} triggers used are not fully efficient and therefore
985 simulated data must be scaled to account for trigger inefficiencies. Trigger effi-
986 ciencies are given by the ratio of the distribution of offline objects before trigger
987 selection and after trigger selection.

988 Uncertainties on small-R jet energy scale and resolution are measured in-situ
989 by calculating the response between data and simulation. This analysis uses a
990 reduced set of JES and JER uncertainties (totaling 30 and 8 systematics, re-
991 spectively). These reduced sets of systematics are calculated using a principal
992 component analysis, yield largely uncorrelated independent systematics. These
993 uncertainties account for the dependence on p_T , η , μ , flavor response and global
994 sequential corrections. Systematic uncertainties associated with b -tagging are also
995 considered. These systematics are evaluated as uncertainties on the scale factor
996 which account for the difference in b -tagging efficiencies in data and MC, and the
997 flavor dependence (between b, c, and light jets).

998 The uncertainty on the p_T scale of the large-R jets is determined by comparing
999 the jet's p_T^{calo} to p_T^{track} in di-jet simulation and data. In addition to this uncertain-
1000 ties from tracking, modeling (Pythia vs Herwig), and statistical constraints are
1001 also calculated. The large-R jet p_T resolution is given by smearing the jet p_T with
1002 a Gaussian with a 2% width.

1003 The W/Z -tagging efficiency cannot be evaluated using the Rtrk method as the
1004 TCC algorithm uses track measurements to reconstruct jet substructure variables.
1005 In order to avoid this potential bias, the W/Z -tagging estimated in data using a
1006 control sample and correct by comparing it with simulation. The efficiency to

1007 W/Z -induced signal is estimated by a $t\bar{t}$ control sample, while the efficiency to
1008 single- q/g background is estimated using a dijet sample. The effects of experimen-
1009 tal and theoretical uncertainties on the efficiency scale factor are by taking the
1010 ratio of efficiencies in data and simulation. By taking this ratio the uncertainties
1011 not arising for jet mass and D_2 cancel.

1012 Lepton identification, reconstruction, isolation systematic uncertainties are de-
1013 termined by reconstructing the Z mass peak with a tag and probe method. The
1014 lepton energy and momentum scales are also measured with the Z mass peak.
1015 Additionally, the track-to-vertex association efficiency is used for muons.

1016 As E_T^{miss} is calculated using all the physics objects in the event, all those objects
1017 associated errors result in an uncertainty on E_T^{miss} . Additionally, the unassociated
1018 tracks used to construct E_T^{miss} contribute to the uncertainty on E_T^{miss} .

1019 8.2 Theory Systematics

1020 Theoretical uncertainties for signal and background processes arise from un-
1021 certainties in the parameters used in Monte Carlo simulation. In particular for
1022 the $t\bar{t}$, $W/Z+jets$, and diboson backgrounds and signal samples the QCD scale,
1023 PDF, generator and hadronization uncertainties were evaluated. To assess the
1024 QCD scale uncertainty the renormalization and factorization scales were scaled
1025 up (2.0) and down (0.5) at the event generation stage of sample production. Un-
1026 certainties due to the choice of the parton distribution functions were evaluated
1027 by re-weighting samples from the nominal PDF to a set of error PDFs which ac-
1028 count for the uncertainty of the fits used to produce the PDF set. In addition to
1029 this samples are re-weighted to different PDF sets to account for the arbitrariness
1030 of the PDF choice. The difference between the m_{WV} distributions using differ-
1031 ent event generators is assessed by comparing samples generated with different

1032 generators. Similarly, the uncertainty in hadronization models is account for by
1033 comparing samples created using different hadronization models (e.g. Pythia8 vs.
1034 Herwig7). Figures 8.2 - 8.8 show the impact of these uncertainties on the $t\bar{t}$ and
1035 $W/Z + \text{jets}$ backgrounds.

1036 Additionally, contributions to the diboson background for the VBF analysis
1037 were included in [SOME WAY that is not determined yet].

1038 The normalization of the $t\bar{t}$ and $W+\text{jets}$ processes impact the multijet template
1039 shape. The impact of these normalization is assess by including a shape systematic
1040 on the multijet background from varying the $t\bar{t}$ and $W+\text{jets}$ normalization factors.

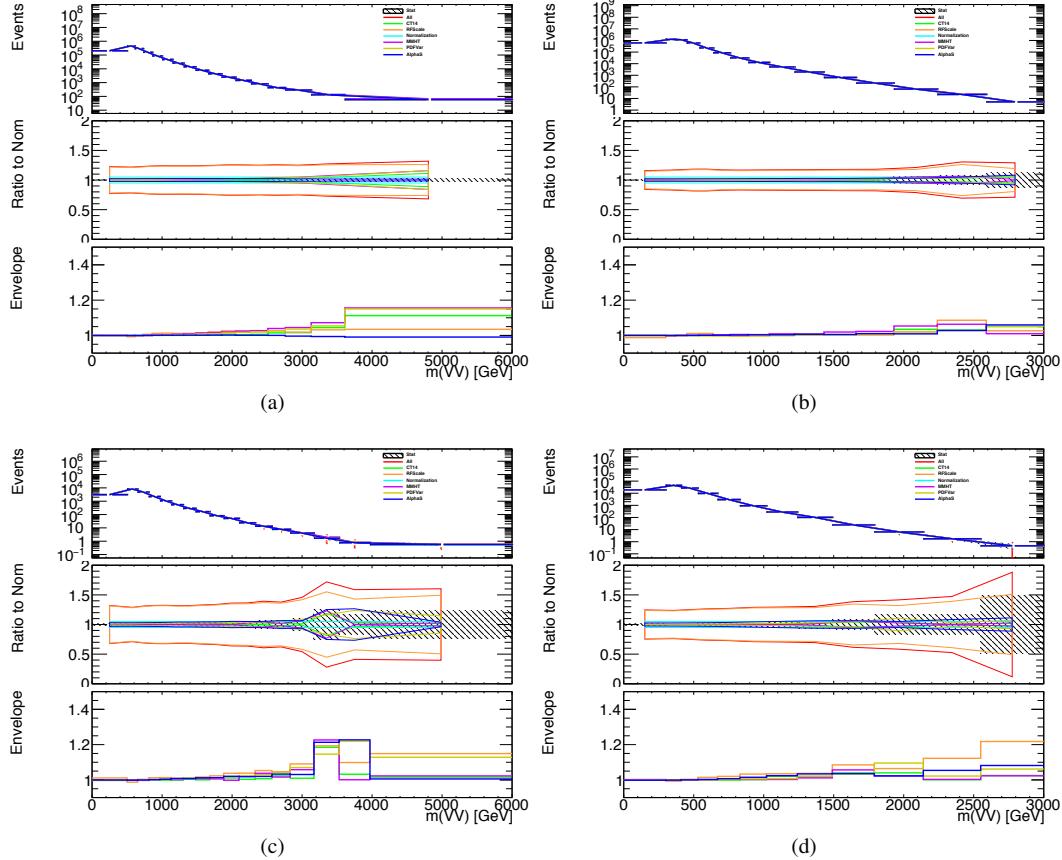

Figure 8.1: The $W/Z + \text{jet}$ systematics for the a) Merged ggF, b) Resolved ggF, c) Merged VBF, and d) Resolved VBF regions. The top subplot shows the nominal and variation distributions/bands, the middle shows the ratio of the two, and the final shows just the shape of the envelope (the final uncertainty).

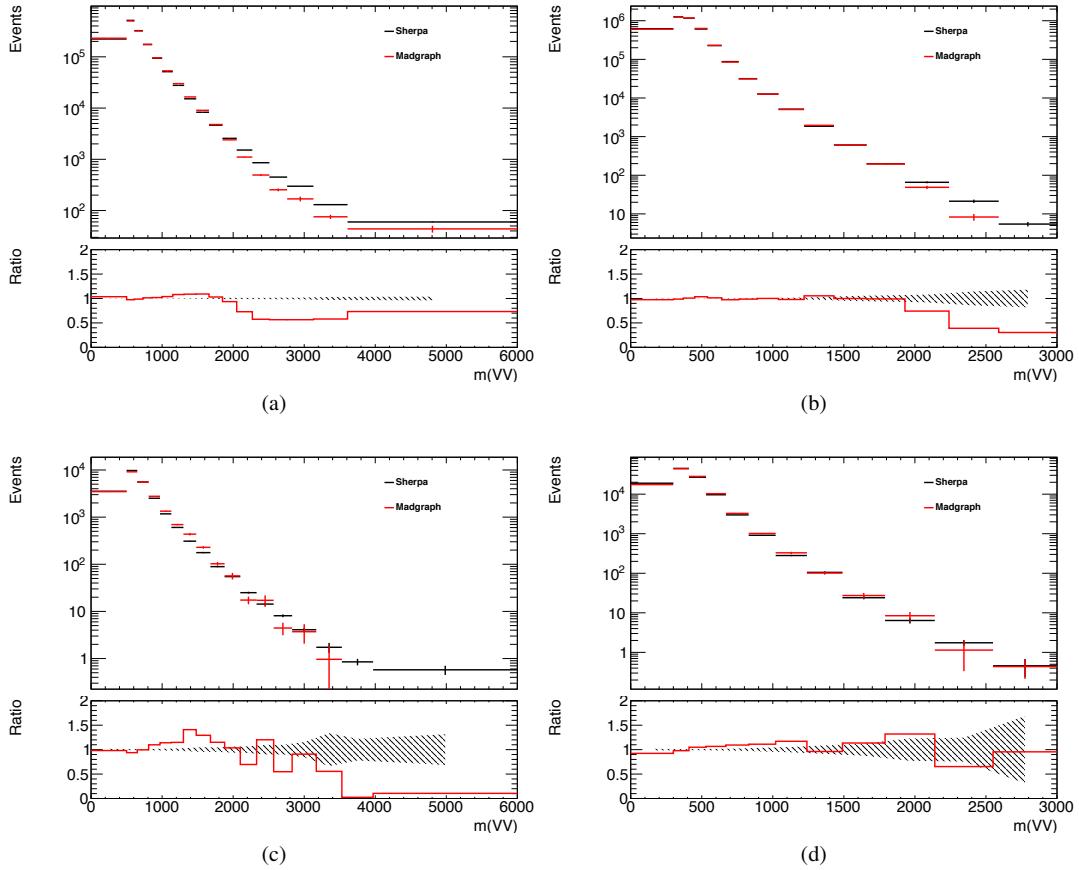

Figure 8.2: The two-point generator comparison between Sherpa and MadGraph for the $W/Z + \text{jet}$ samples in the a) Merged ggF, b) Resolved ggF, c) Merged VBF, and d) Resolved VBF regions. The normalization of the Madgraph sample is set to the Sherpa value to consider only shape effects. The bottom inset shows the ratio of the two.

1041 **Chapter 9**

1042 **Statistical Analysis**

1043 To determine the compatibility of the data collected with the proposed reso-
1044 nances a statistical procedure based on a likelihood function is used. A discovery
1045 test is used to measure the compatibility of the observed data with the back-
1046 ground only hypothesis. If the observed data is sufficiently incompatible with the
1047 background only hypothesis, this could indicate a discovery. In the absence of
1048 discovery, upper limits on the signal strength parameter, μ , are assessed using the
1049 CLs method.

1050 **9.1 Likelihood Function Definition**

1051 The likelihood function is product of Poisson probabilities for all analysis bins
1052 and systematic constraints:

$$\mathcal{L}(\mu, \boldsymbol{\theta}) = \prod_c \prod_i \frac{(\mu s_{ci}(\boldsymbol{\theta}) + b_{ci}(\boldsymbol{\theta}))^{n_{ci}}}{n_{ci}!} e^{-(\mu s_{ci}(\boldsymbol{\theta}) + b_{ci}(\boldsymbol{\theta}))} \prod_k (\theta'_k | \theta_k) \quad (9.1)$$

1053 Here c are the analysis channels considered and i runs over all the $m_{\ell\nu qq}$ bins
1054 used in the fit. The signal strength parameter, μ , multiplies the expected signal

yield in each analysis bin, s_{ci} . The background content for channel c and bin i is given by b_{ci} . The dependence of signal and background predictions on systematic uncertainties is described by the aforementioned set of nuisance parameters $\boldsymbol{\theta}$, which are parameterized by Gaussian or log-normal priors denoted here as θ_k . Statistical uncertainties of the simulated bin contents are also included as systematic uncertainties. Most systematics are correlated among all the analysis regions and considered to be independent from each other. The validity of this assumption is checked by evaluating the covariance of nuisance parameters.

9.2 Fit Configuration

The binning of $m_{\ell\nu qq}$ in signal regions for likelihood fit is determined by the statistical uncertainty of signal mass width. For each signal mass point, the signal mass resolution is given by the fitted Gaussian width of the $m_{\ell\nu qq}$. The fitted signal widths are then fit to a line to give a parameterized signal mass width, as shown in Figures 9.1 and 9.2. Bin widths are set first to this parameterized signal mass resolution. Then if the statistical uncertainty of the data or simulated background is more than 50%, bins are merged until the statistical uncertainty is less than 50%. All control regions contain only a single bin.

For this analysis, each signal model fits the Merged and Resolved channels for the relevant signal production mode simultaneously. The control regions are used to extract $W+jets$ and $t\bar{t}$ backgrounds normalizations in the signal regions.

Systematics may be affected by low statistics, leading to unsmooth m_{VV} distributions with unphysically large fluctuations. This can lead to artificial pulls and constraints in the fit. To remove such issues a multi-step smoothing procedure is applied to all systematic variation distributions in all regions. First, distributions are rebinned until the statistical error per bin is at least 5%. Next

1080 all local extrema are identified. The bins around smallest extrema are iteratively
1081 merged until only four local extrema remain. Then distributions are rebinned so
1082 that statistical uncertainties in each bin are $< 5\%$.

1083 For some systematics, up and down variations may be in the same direction
1084 with respect to the nominal distributions, leading to asymmetric distributions.
1085 This causes the variations to not cover the nominal choice, and the interpretation
1086 of the confidence interval is skewed. This asymmetry may also lead to uncon-
1087 strained systematics in the fit. To handle such asymmetric systematics, if the up
1088 and down variation for a given systematic are in the same direction for at least
1089 three m_{VV} bins the variation is averaged for those bins. The averaging proce-
1090 dure replaces bin-by-bin the up and down variation bins by $b_{\pm}^{new} = b_{nom} \pm \frac{|b_+ - b_-|}{2}$,
1091 where b_{nom} is the nominal bin content and b_{\pm} are the original up and down varia-
1092 tion bin content. The same procedure is also applied to any variations where the
1093 integral of the difference between the up/down variation and the nominal distri-
1094 bution is twice that of the other down/up variation, further ensuring variations
1095 are symmetric around the nominal distribution.

1096 Finally, systematics that have a negligible effect on the m_{VV} distribution are
1097 not considered in the fit. Shape systematics where no bin in the variational dis-
1098 tribution deviates more than 1% from the nominal distribution (after normalizing
1099 all histograms to the nominal) are not included in the fit. Also, statistical bin
1100 uncertainties $< 1\%$ are ignored.

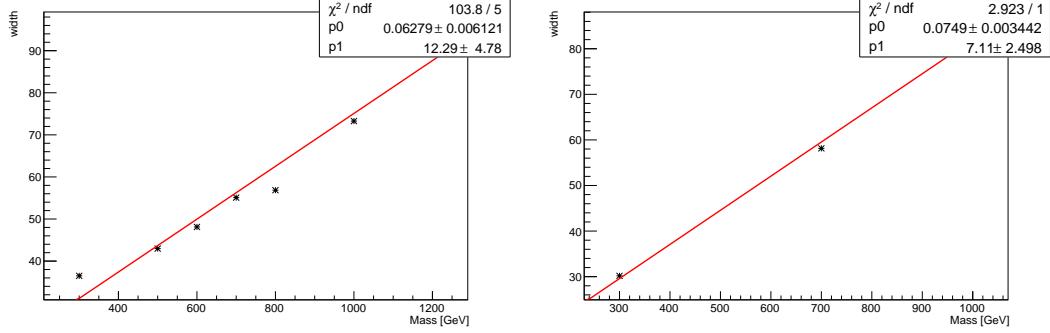

Figure 9.1: The HVT signal mass resolution as a function of mass fit with a straight line in the Resolved ggF region (left) and VBF (right) region.

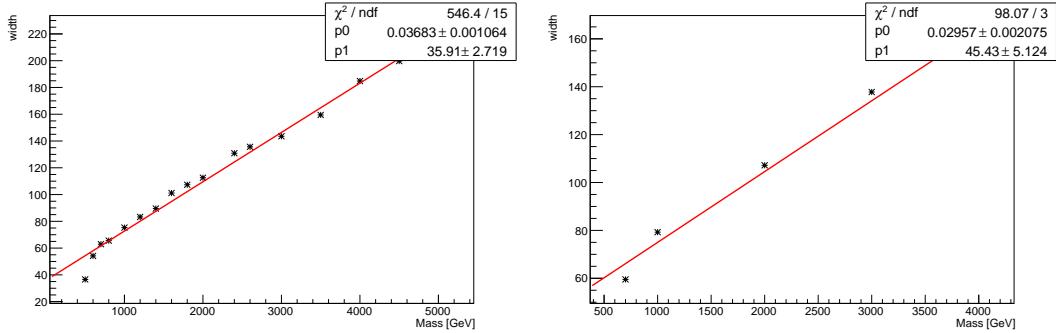

Figure 9.2: The HVT signal mass resolution as a function of mass fit with a straight line in the Merged ggF region (left) and VBF (right) region.

1101 9.3 Best Fit μ

1102 The best fit signal strength parameter is denoted by $\hat{\mu}$ and calculated by
 1103 maximizing the likelihood function with respect to all systematics and μ . The
 1104 corresponding set of systematics that maximize the likelihood are given by $\hat{\mu}$.
 1105 The first term in the likelihood is maximized when the expected number of signal
 1106 and background events is equal to the number of events in data ($n_{ci} = \mu s_{ci} +$
 1107 b_{ci}). Thus, by maximizing the likelihood, the fit determines values of μ and θ
 1108 that give the best agreement between expected and measured event yields. The

1109 second term in the likelihood is a penalty term which decreases the likelihood
1110 when systematics are shifted from their nominal values. This prevents the fit
1111 from profiling systematics in unphysical ways to maximize the likelihood. The
1112 uncertainty on μ is calculated by varying μ up and down until the natural log of
1113 the likelihood function shifts by one-half.

1114 9.4 Discovery Test

1115 To determine if the observed dataset is consistent with tested signal model a
1116 likelihood ratio is constructed:

$$\lambda(\mu) = \frac{\mathcal{L}(\mu, \hat{\theta}_\mu)}{\mathcal{L}(\hat{\mu}, \hat{\theta})} \quad (9.2)$$

1117 The denominator in this equation is the maximized value of \mathcal{L} over all system-
1118 atics and μ . The numerator is the maximized likelihood over all systematics for
1119 a given μ value, where the maximized systematics are given by $\hat{\mu}_\mu$. To test for
1120 the existence of signal the observed dataset the null hypothesis (H_0) is defined as
1121 the background only hypothesis and the alternate hypothesis includes signal and
1122 background (H_1). This test quantifies the compatibility of observed data with
1123 H_0 by calculating a p-value representing the probability of observing data as dis-
1124 crepant or more than the observed data under the H_0 . The test statistic used to
1125 calculate this p-value is given by (r_0):

$$r_0 = \begin{cases} -2 \ln \lambda(0), \hat{\mu} > 0 \\ +2 \ln \lambda(0), \hat{\mu} < 0 \end{cases} \quad (9.3)$$

1126 The expected distribution of the the test statistic under H_0 ($f(r_0|0)$) is used to
1127 calculate the p-value:

$$p_0 = \int_{r_0, obs}^{\infty} f(r_0 | 0) dr_0 \quad (9.4)$$

1128 Small p-values indicate the observed data is poorly described by H_0 . This
 1129 equivalent Z-score of a given p-value is usually used to further quantify the agree-
 1130 ment between the observed data and H_0 . The Z-score is given by the number of
 1131 standard deviations away from the mean of a Gaussian distribution, the integral
 1132 of the upper tail of the distribution would equal the p-value. Mathematically:

$$Z = \Phi^{-1}(1 - p_0) \quad (9.5)$$

1133 where Φ is the Gaussian cumulative distribution function. The statistical
 1134 significance of these tests are expressed as the Z -score. In particle physics, 3σ is
 1135 considered evidence for new phenomena and 5σ is the threshold for discovery.

1136 9.5 Exclusion Limits

1137 In the absence of discovery, upper limits on the signal strength, μ are set using
 1138 the CLs method [cite P60]. The test statistic for this test, q_μ , is constructed as:

$$\tilde{\lambda}_\mu = \begin{cases} \frac{\mathcal{L}(\mu, \hat{\theta}_\mu)}{\mathcal{L}(\hat{\mu}, \hat{\theta})}, \hat{\mu} > 0 \\ \frac{\mathcal{L}(\mu, \hat{\theta}_\mu)}{\mathcal{L}(0, \hat{\theta}_0)}, \hat{\mu} < 0 \end{cases} \quad (9.6)$$

$$\tilde{q}_\mu = \begin{cases} -2 \ln \tilde{\lambda}(\mu), \hat{\mu} < \mu \\ +2 \ln \tilde{\lambda}(\mu), \hat{\mu} > \mu \end{cases} \quad (9.7)$$

1139 As defined, larger values of q_μ correspond to increasing incompatibility between
 1140 the observed data and the background + signal hypothesis. The observed value
 1141 of the test statistic, $q_{\mu, obs}$, is then compared to its expected distribution, f , to

1142 calculate p-values to assess the likelihood of the background+signal hypothesis.

1143 Using these distributions, CL_s values are computed as:

$$CL_{s+b} = \int_{q_{\mu,obs}}^{\infty} f(q_{\mu}|\mu) dq_{\mu} \quad (9.8)$$

1144

$$CL_b = \int_{q_0^{obs}}^{\infty} f(q_{\mu}|\mu = 0) dq_{\mu} \quad (9.9)$$

1145

$$CL_s = \frac{CL_{s+b}}{CL_b} \quad (9.10)$$

1146 CL_{s+b} is the p-value for the signal + background hypothesis and CL_b is the
1147 p-value for the background only hypothesis. The CL_s value is interpreted as
1148 the probability to observe the background + signal hypothesis normalized to the
1149 probability of background-only hypothesis. Normalizing by CL_b prevents setting
1150 artificially strong exclusion limits due to downward fluctuations in data.

1151 In this analysis, μ values are scanned for each bin in the fit to find the μ value
1152 that yields $CL_s=0.05$, meaning the likelihood of finding data more incompatible
1153 with the signal+background hypothesis (relative to the background only hypoth-
1154 esis) is 5%. The 95% upper limit on the cross section is then calculated as the
1155 product of the μ value found, branching ratio, and theory cross section.

Part IV

Results

1157

1158 **Chapter 10**

1159 **Statistical Interpretation**

1160 **10.1 Discovery Tests**

1161 To test for the existence of signal in the observed dataset, the discovery tests
1162 discussed earlier are used to calculate p-values as a function of resonance mass.
1163 The results of these tests are shown in Figures 10.1 - 10.5. Across the different
1164 DY signals the largest excesses are $\sim 2.2\sigma$ at 600 GeV and 1.8σ at 2 TeV. The
1165 largest excesses for VBF signals are $< 2.5\sigma$ at for 1 TeV resonances. As these
1166 deviations do not constitute discoveries, upper limits on μ are calculated.

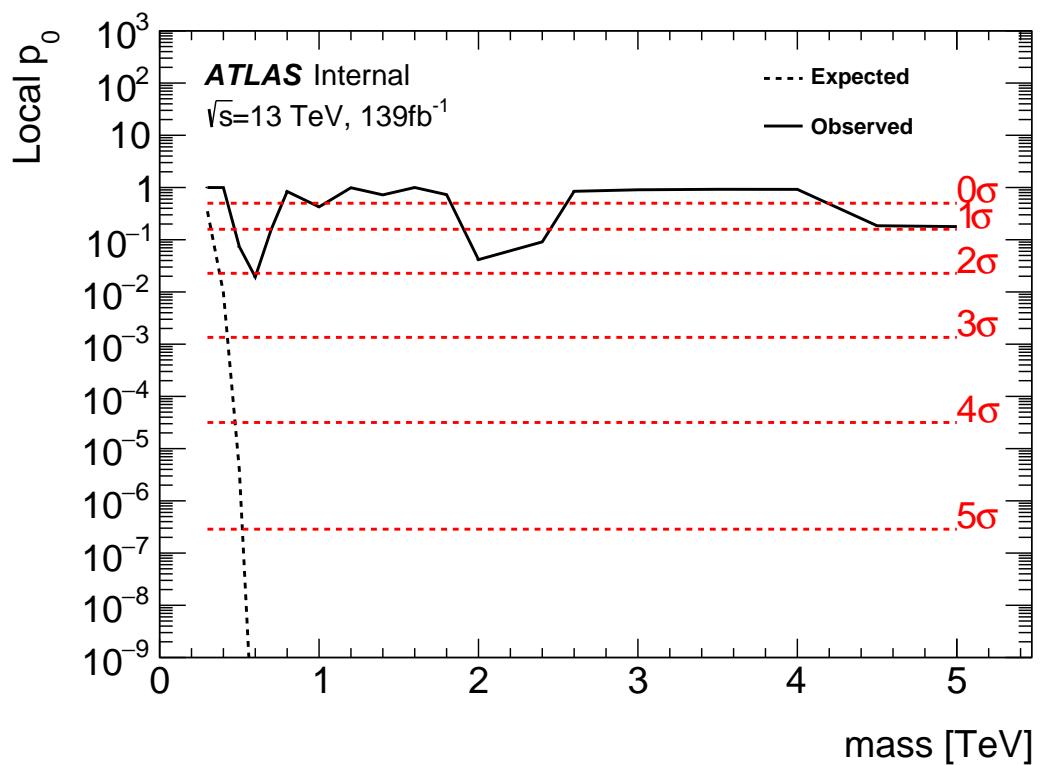

Figure 10.1: These plots show the measured p_0 value as a function of resonance mass for HVT Z' DY production.

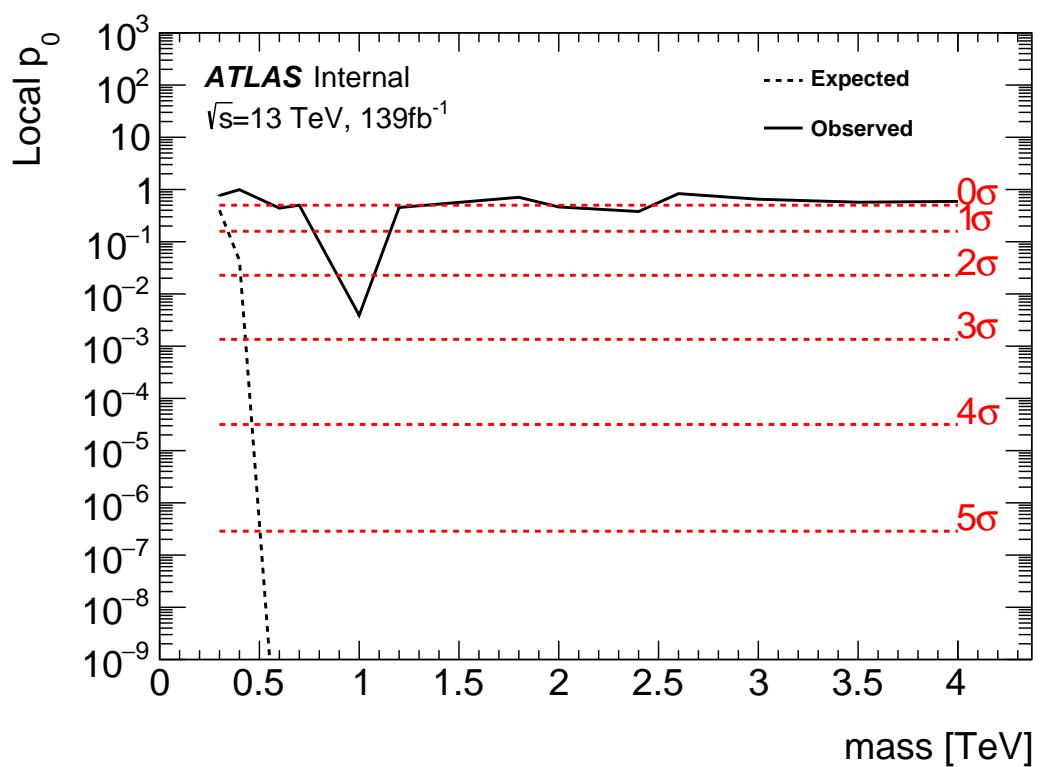

Figure 10.2: These plots show the measured p_0 value as a function of resonance mass for HVT Z' VBF production.

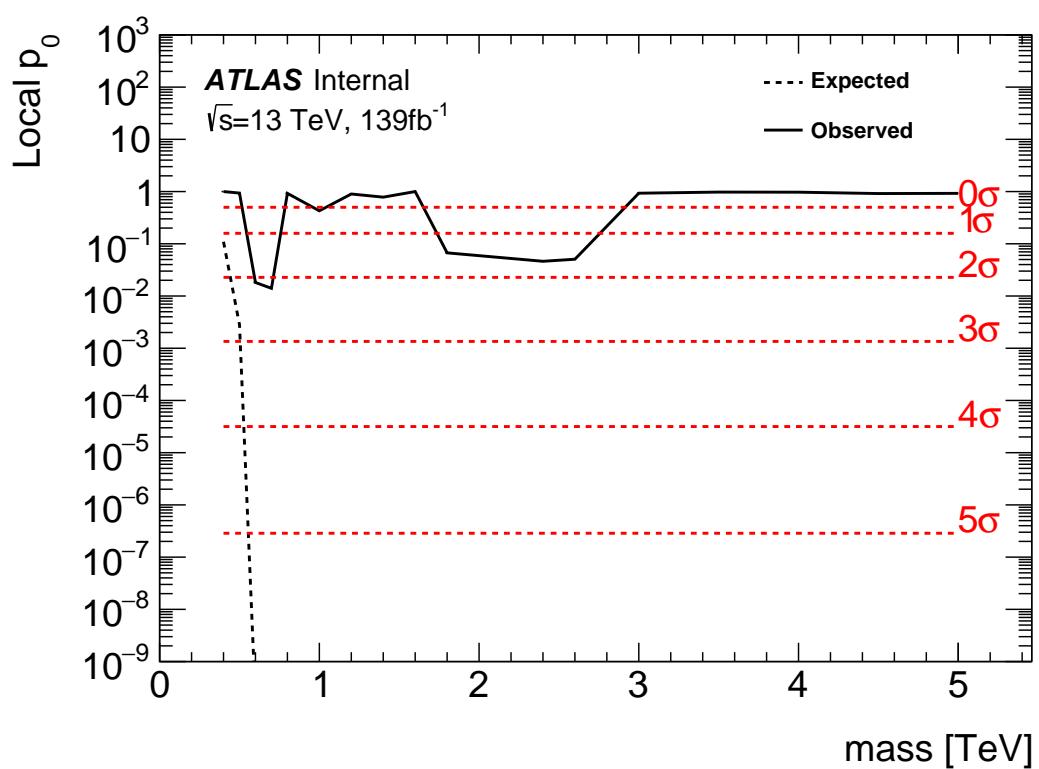

Figure 10.3: These plots show the measured p_0 value as a function of resonance mass for HVT W' DY production.

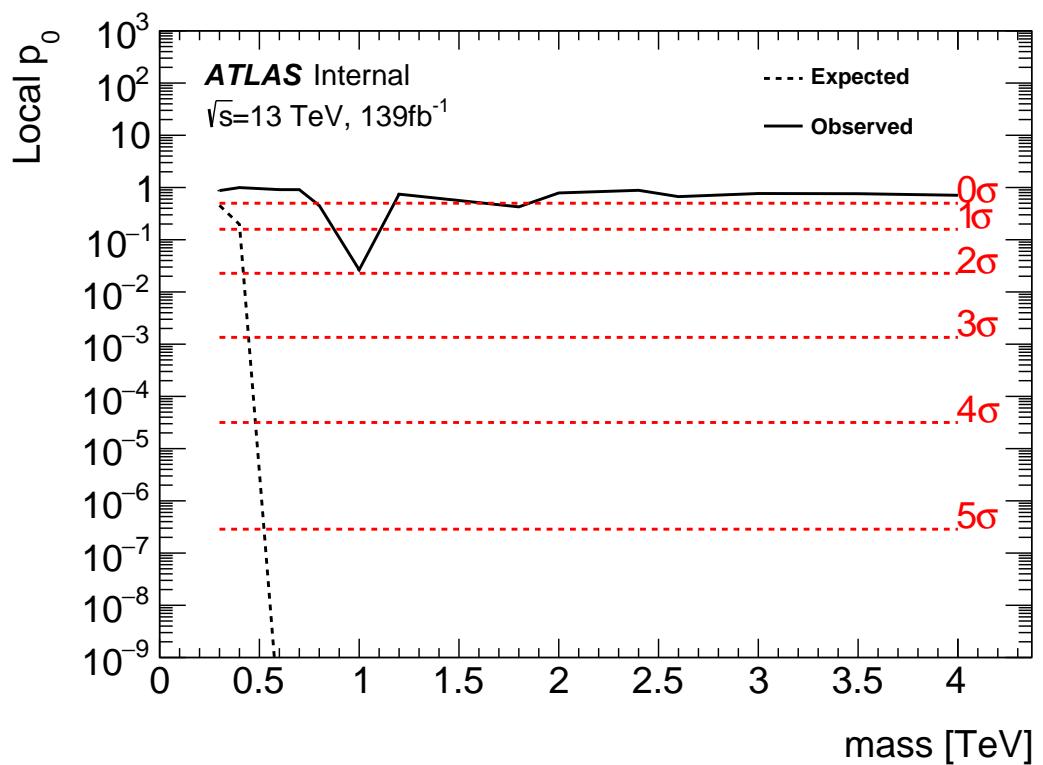

Figure 10.4: These plots show the measured p_0 value as a function of resonance mass for HVT W' VBF production.

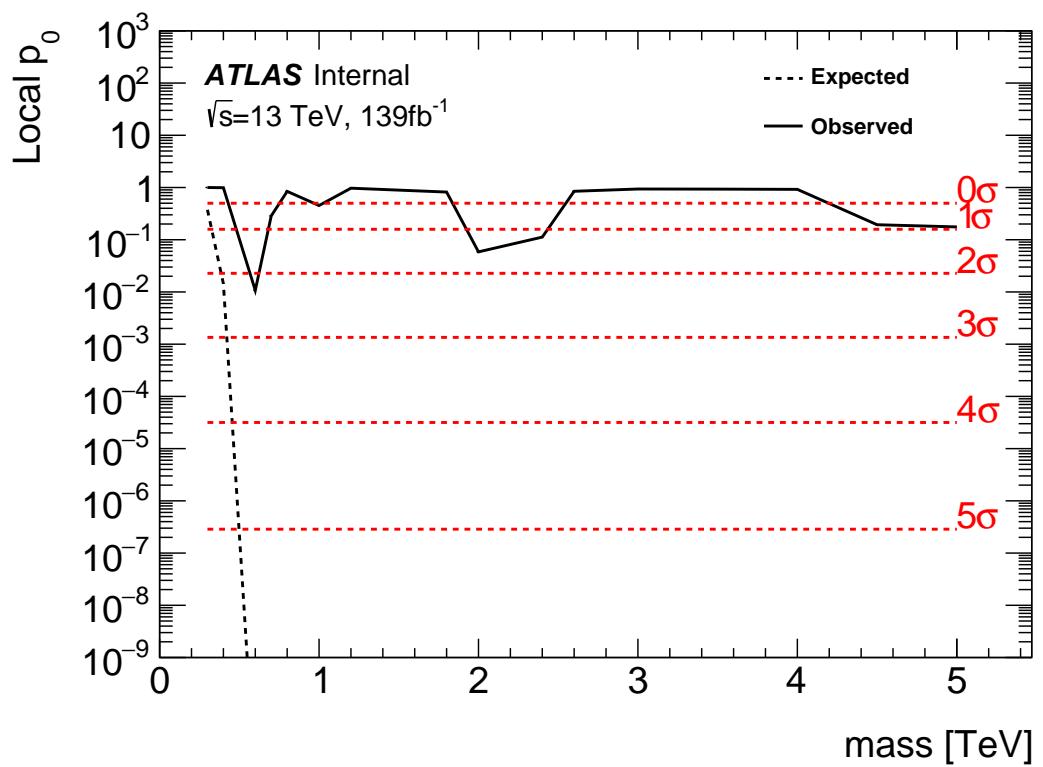

Figure 10.5: These plots show the measured p_0 value as a function of resonance mass for the RS Graviton DY production.

1167 10.2 Systematic Profiling and Correlations

1168 The ranked systematics and their fitted values are shown for the different anal-
 1169 ysis regions in Figure 10.6 - 10.8. Note that background normalizations for $W+jets$
 1170 and $t\bar{t}$ are left free to float in the fit. This means the nominal normalization val-
 1171 ues are at one and the uncertainties are not plotted in the ranked plots. Overall,
 1172 systematics are not pulled outside their uncertainties, especially for highly ranked
 1173 nuisance parameters.

1174 The correlation between systematics are shown in Figures ???. Correlations
 1175 between background normalization are expected. The remaining systematic cor-
 relations are not very strong or unexpected.

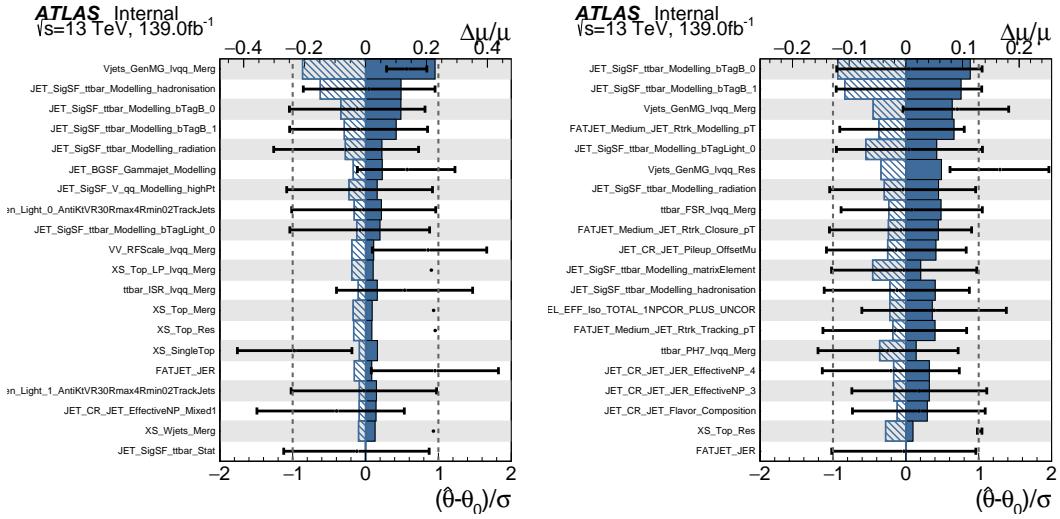

Figure 10.6: Ranked systematics and their fitted values for WW DY (right) and VBF (left) selections.

1176

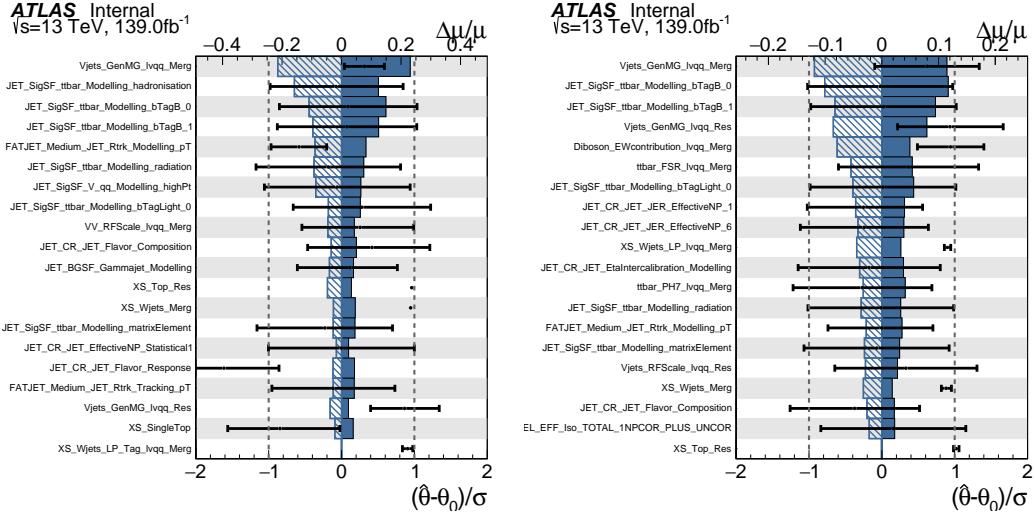

Figure 10.7: Ranked systematics and their fitted values for WZ DY (right) and VBF (left) selections.

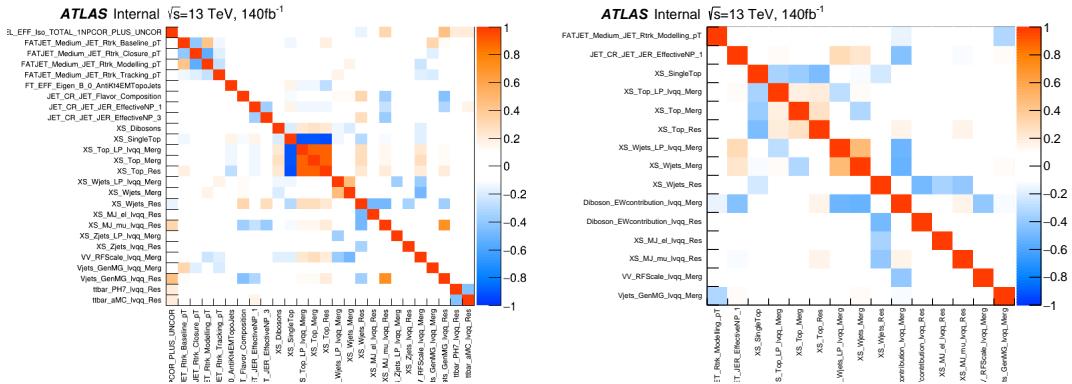

Figure 10.8: Correlations between systematics for WW DY (right) and VBF (left) selections.

1177 10.3 Expected and Measured Yields

1178 The yield tables for the four analysis regions are shown in Tables ?? - ?? . The
 1179 fitted background normalizations are shown in Tables ??-?? . The control region
 1180 $m_{\ell\nu qq}$ distributions are shown in Figures 10.9 - 10.12. The signal region $m_{\ell\nu qq}$
 1181 distributions are shown in Figures 10.13 - ?? .

1182 10.4 Limits

1183 Using the exclusion limits tests discussed previously, exclusion limits are set
 1184 on μ and consequently cross-sections for different signal models. Exclusion limits
 1185 for the models considered are shown in Figure 10.18 - 10.20. These limits exclude
 1186 HVT Model A $W' < \text{blah}$ and $Z' < \text{blah}$ and Model B $W' < \text{blah}$ and $Z' < \text{blah}$.
 1187 Randall Sundrum Gravitons are excluded for masses below blah.

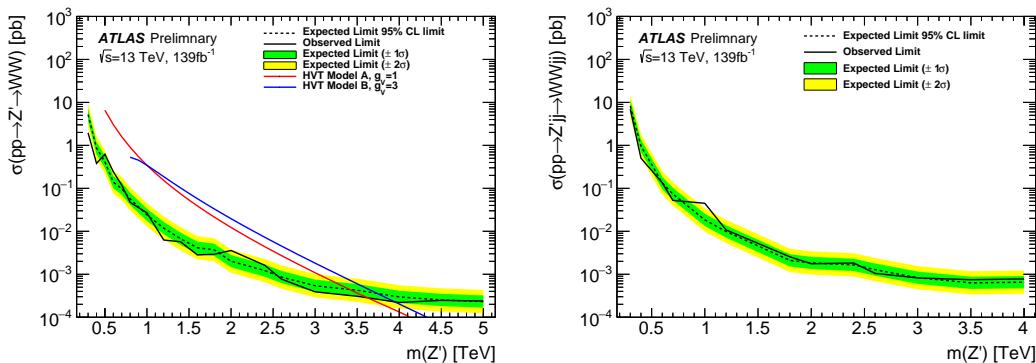

Figure 10.18: This figure shows theory, expected and observed limits for HVT W' DY (left) and VBF (right) production.

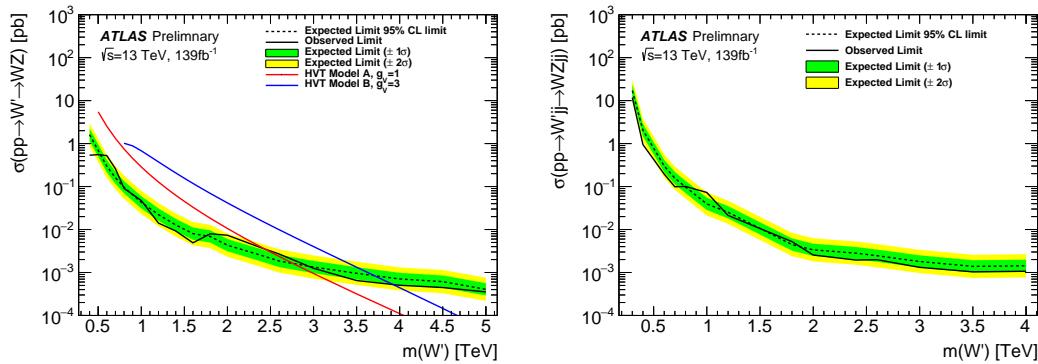

Figure 10.19: This figure shows theory, expected and observed limits for HVT Z' DY (left) and VBF (right) production.

1188

Quark and Gluon Tagging

1189

₁₁₉₀ **Chapter 11**

₁₁₉₁ **Prospects**

₁₁₉₂ For the resolved analysis, signal jets are quark enriched and background jets are
₁₁₉₃ gluon dominated. By classifying jets in the event as quark or gluon initiated, less
₁₁₉₄ background would contaminate the signal region. Figure 11.1 shows the PDGID
₁₁₉₅ for the truth parton matched to the jet (meaning the highest energy parton in
₁₁₉₆ the jet catchment area) in events passing the resolved signal region selections.
₁₁₉₇ PDGID = -1 corresponds to pileup jets, $0 < \text{PDGID} < 6$ correspond to quarks
₁₁₉₈ and $\text{PDGID} = 21$ corresponds to gluons. From this Figure, it is evident that a
₁₁₉₉ notable fraction of the background that contaminates the signal region contains
₁₂₀₀ gluon jets, especially for the sub-leading jet.

₁₂₀₁ As gluons jets have more constituents and therefore more tracks (n_{trk}), the
₁₂₀₂ background jets have more tracks than the signal jets. This is shown in Fig-
₁₂₀₃ ure 11.2. Therefore, by cutting on the number of tracks in a jet, quark and gluon
₁₂₀₄ jets may be distinguished (i.e. jets with less than a given number of tracks are
₁₂₀₅ classified as a quark, otherwise the jet is classified as a gluon.) Moreover, as the
₁₂₀₆ momentum of the jet increases the number of tracks also increases logarithmically.
₁₂₀₇ Therefore by applying a cut on the number of tracks that scales with the $\ln(p_T)$
₁₂₀₈ is more powerful than a threshold cut on the number of tracks. Figure 11.3-

1209 Figure 11.6 show normalized heat maps of $\ln(p_T)$ vs the number of reconstructed
1210 tracks for the background and a 300 GeV Z' signal. In these plots it is evident
1211 that the number of tracks in the background jets grows more quickly with $\ln(p_T)$
1212 than for the signal jets. This is expected given that the signal is quark dominated
1213 and the background is gluon dominated.

1214 In Figure 11.8 is the ROC Curve for quark gluon tagging with cut on the
1215 number of tracks in a jet that depends on $\ln(p_T)$. The sum of the backgrounds in
1216 the signal region were used for this curve. Here the quark tagging efficiency is the
1217 ratio of quarks tagged as quarks to the total number of quarks in the signal region.
1218 The gluon rejection is calculated as the reciprocal of the gluon tagging efficiency.
1219 Choosing a 90 efficient working point with a rejection of 1.4 corresponds to a slope
1220 of 4 and intercept of -5. Focusing on the background in Figure 11.9, this cut helps
1221 minimize gluon contamination in the signal region. Also, from these heat maps it
1222 is obvious that the number of tracks in gluon jets grows more quickly than those
1223 in quark jets.

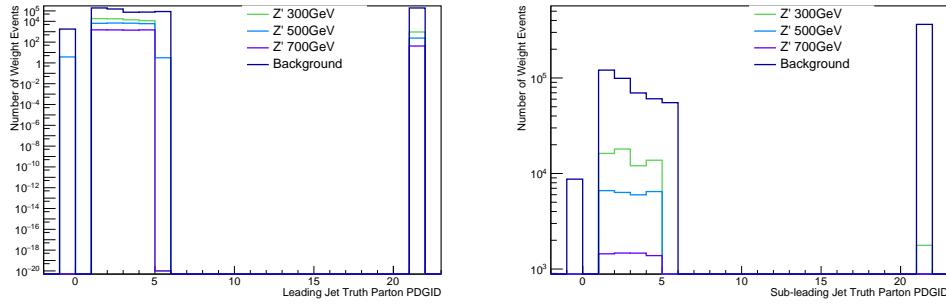

Figure 11.1: PDGID of the truth-level parton matched to the small-R jets passing the Resolved GGF WW Signal Region selections for the (a) Leading (b) Sub-Leading jets . These distributions are shown for 300, 500, and 700GeV Z' signals and the background.

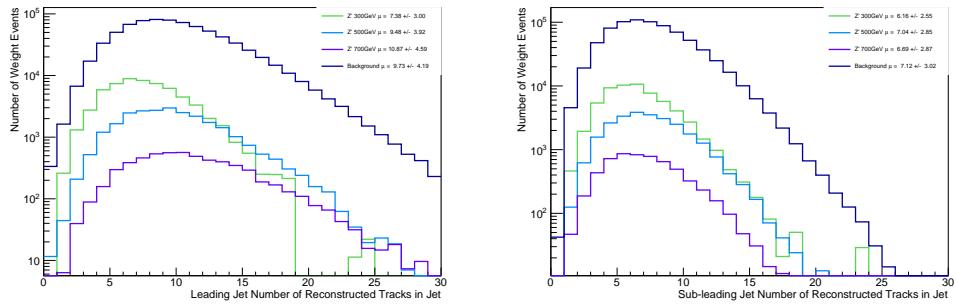

Figure 11.2: The number of tracks in small-R jets in events passing the Resolved GGF WW Signal Region selections for the (a) Leading (b) Sub-Leading jets. These distributions are shown for 300, 500, and 700GeV Z' signals and the background.

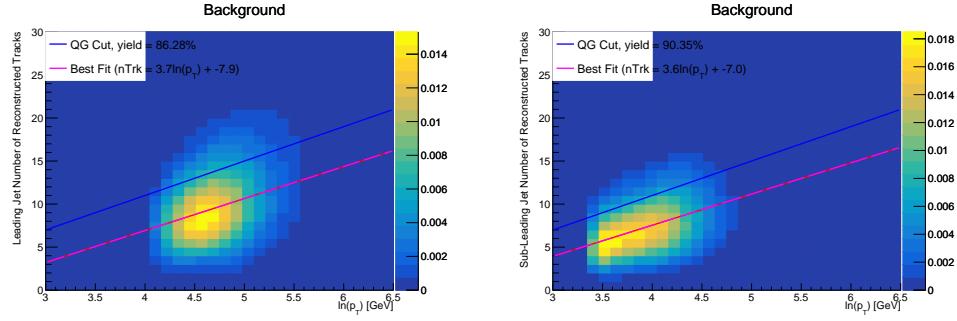

Figure 11.3: The number of tracks in background small-R jets in events passing the Resolved GGF WW Signal region selection vs. $\ln(p_T)$ for (a)Leading (b) Sub-Leading jets. The best fit line for the distribution is also shown, as well as the percentage of jets that pass a cut of number of tracks $< 4 \times \ln(p_T) - 5$. Note the number of total entries in these plots has been normalized to one.

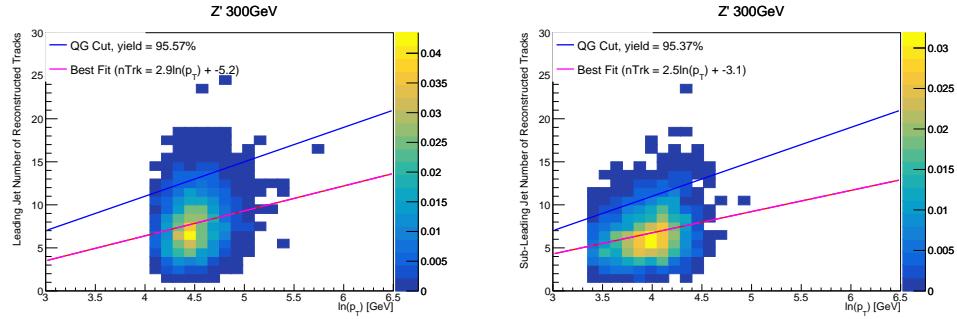

Figure 11.4: The number of tracks in small-R jets in 300GeV Z' events passing the Resolved GGF WW Signal region selection vs. $\ln(p_T)$ for (a)Leading (b) Sub-Leading jets. The best fit line for the distribution is also shown, as well as the percentage of jets that pass a cut of number of tracks $< 4 \times \ln(p_T) - 5$. Note the number of total entries in these plots has been normalized to one.

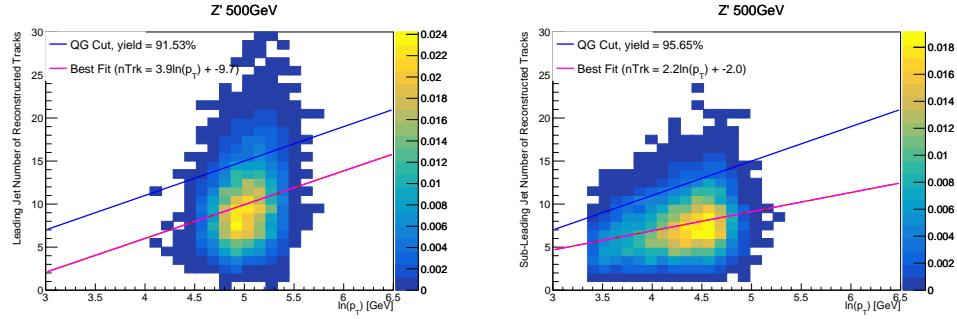

Figure 11.5: The number of tracks in small-R jets in 500GeV Z' events passing the Resolved GGF WW Signal region selection vs. $\ln(p_T)$ for (a)Leading (b) Sub-Leading jets. The best fit line for the distribution is also shown, as well as the percentage of jets that pass a cut of number of tracks $< 4 \times \ln(p_T) - 5$. Note the number of total entries in these plots has been normalized to one.

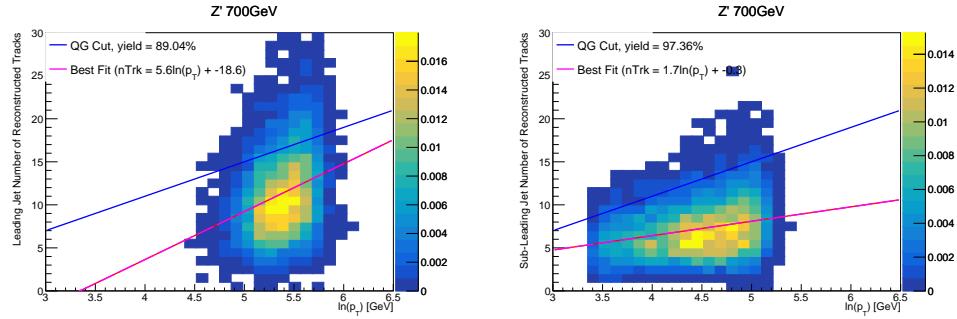

Figure 11.6: The number of tracks in small-R jets in 700GeV Z' events passing the Resolved GGF WW Signal region selection vs. $\ln(p_T)$ for (a)Leading (b) Sub-Leading jets. The best fit line for the distribution is also shown, as well as the percentage of jets that pass a cut of number of tracks $< 4 \times \ln(p_T) - 5$. Note the number of total entries in these plots has been normalized to one.

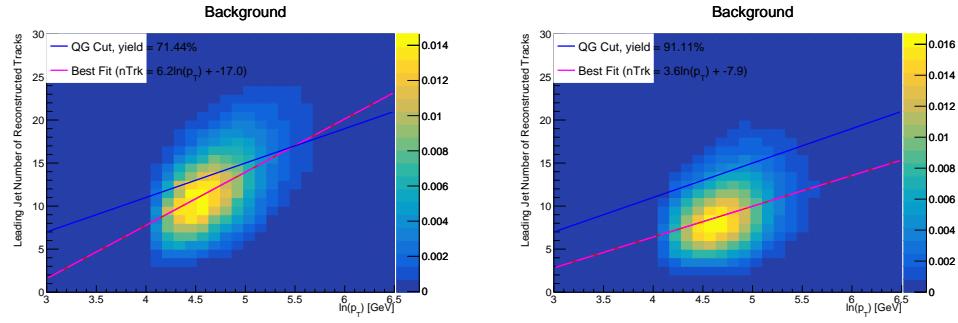

Figure 11.7: The number of tracks in leading small-R jets in background events passing the Resolved GGF WW Signal region selection vs. $\ln(p_T)$ for (a)Gluons (b) Quarks jets. The best fit line for the distribution is also shown, as well as the percentage of jets that pass a cut of number of tracks $< 4 \times \ln(p_T) - 5$.Note the number of total entries in these plots has been normalized to one.

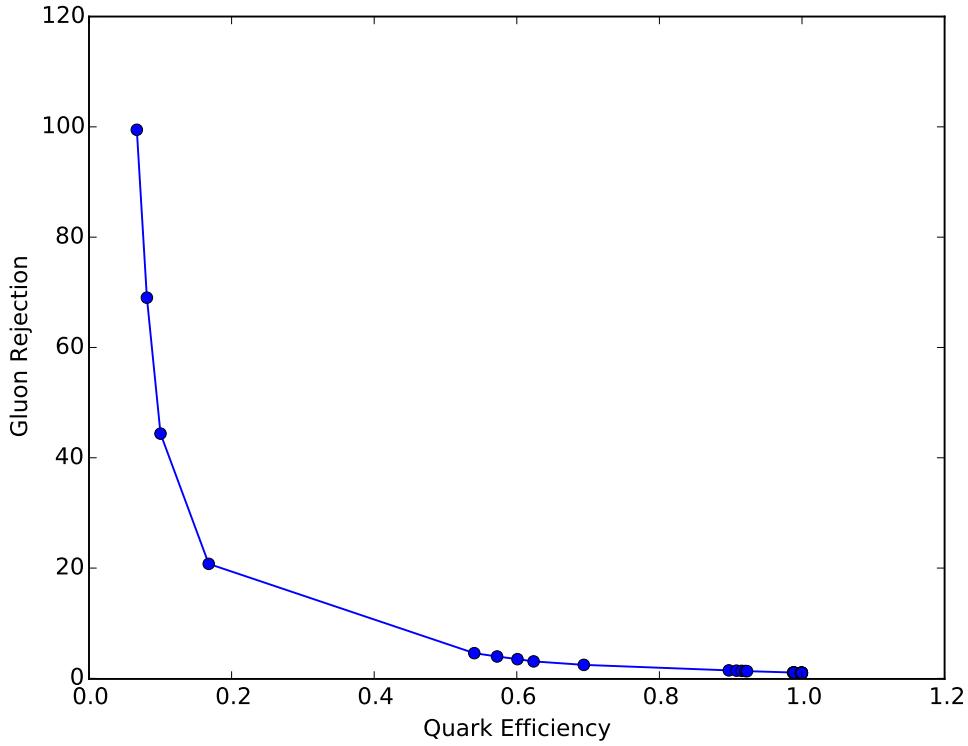

Figure 11.8: ROC Curve for Quark and Gluon Tagging with a cut on the number of tracks that depends on the $\ln(p_T)$.

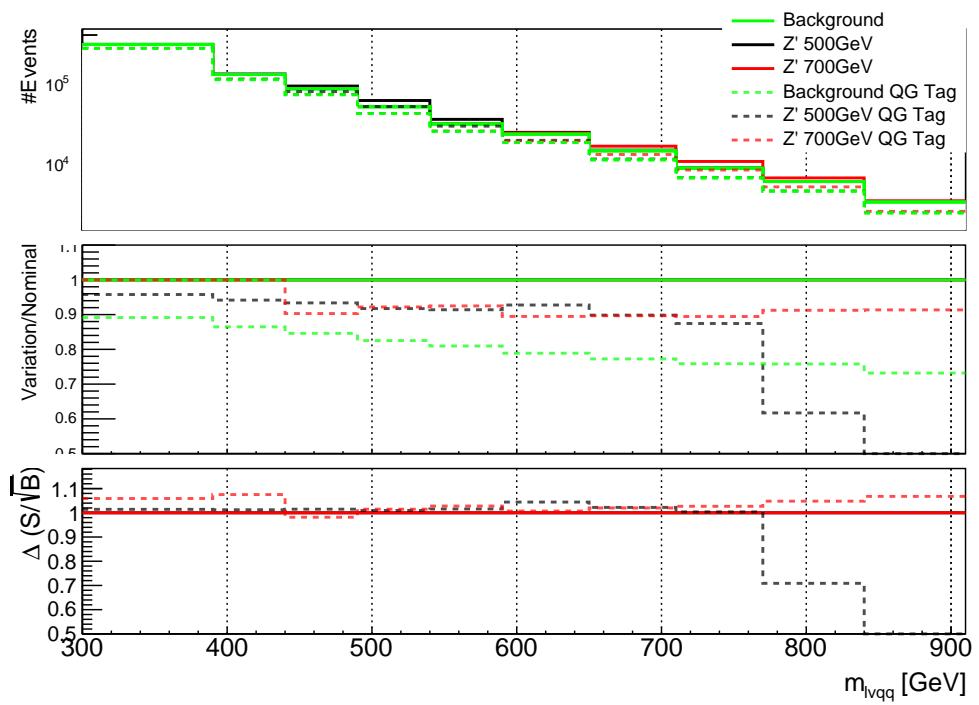

Figure 11.9: The top panel shows the distribution of m_{lvqq} with and without quark gluon tagging. The middle panel shows the ratio of the signals and backgrounds with and without quark gluon tagging. The bottom panel shows the change in S/\sqrt{B} with quark gluon tagging.

₁₂₂₄ **Chapter 12**

₁₂₂₅ **n_{trk} Calibration**

₁₂₂₆ As tagger based on nTrk cuts on the number of tracks in jets, a quantity that
₁₂₂₇ is not known with infinite precision, relevant systematic uncertainties must be
₁₂₂₈ evaluated. The sources of uncertainty in n_{trk} may be split into modeling and
₁₂₂₉ experimental uncertainties.

₁₂₃₀ Modeling uncertainties are obtained by assessing PDF and ME uncertainties
₁₂₃₁ on the number of charged particles in particle-level jets in dijet events. The
₁₂₃₂ number of charged particles as a function of jet p_T is calculated using an Iterative
₁₂₃₃ Bayesian (IB) technique [cite paper].

₁₂₃₄ This measurement ([7]) uses the ATLAS 2012 pp collision dataset, correspond-
₁₂₃₅ ing to $20.3/\text{fb}$ at center-of-mass energy $\sqrt{s} = 8\text{TeV}$. Monte Carlo (MC) samples
₁₂₃₆ are used to determine the response matrix. The MC sample is a dijet sample gen-
₁₂₃₇ erated with Pythia 8.175 using CT10 PDF and AU2 tune. The anti- k_T algorithm
₁₂₃₈ is used to cluster jets with a radius parameter $R = 0.4$. Jets are required to have
₁₂₃₉ $|\eta| < 2.1$. Tracks in jets are required to have $p_T > 500\text{MeV}$, $|\eta| < 2.5$, track-fit
₁₂₄₀ $\chi^2 < 3.0$ and originate from the primary vertex. Matching tracks to jets is accom-
₁₂₄₁ plished using ghost-association [cite]. In this technique, jets are re-clustered with
₁₂₄₂ the track collection augmented with "ghost" versions of tracks. These "ghosts"

1243 tracks have the same direction as their parent track, but infinitesimal track p_T .
1244 This insures meta-jet properties (e.g. η , p_T , etc) are unchanged. A track is
1245 matched to a jet if it's ghost version remains in the jet after re-clustering. Further
1246 details of the data, object, and event selection may be found in [cite 35].

1247 To select dijet topologies events are required to have at least two jets with
1248 $p_T > 50\text{GeV}$ that are relatively well-balanced ($p_T^{\text{lead}}/p_T^{\text{sub-lead}} < 1.5$).

1249 In the IB technique, the prior distribution and number of iterations are the
1250 inputs [cite Bayesian paper]. The IB response matrix connects number of charged
1251 particles to the number of tracks in jets determined using the simulated samples.
1252 This response matrix is used to unfold data to extract the n_c . Before applying
1253 the response matrix a fake factor is applied. This accounts for jets that pass
1254 detector level selections, but not particle level selections. Following this, the IB
1255 method iteratively applies the response matrix using the nominal Pythia 8.175
1256 sample as a prior. The number of IB iterations is chosen to minimize unfolding
1257 bias and statistical fluctuations. For this measurement four iterations was found
1258 to be optimal by minimizing the unfolding bias from pseudodata simulated with
1259 Herwig++ with a prior from Pythia 8 AU2. Finally, the inefficiency factor is
1260 applied to account for events passing particle level selection but not detector
1261 level, yielding the unfolded nCharged distribution.

1262 This process is prone to three main sources of bias: response matrix, correction
1263 factor, and unfolding procedure uncertainties. The response matrix is sensitive to
1264 experimental uncertainties impacting jet track reconstruction and calorimeter jet
1265 p_T . Correction factors are also sensitive to experimental uncertainties (e.g. JES)
1266 as such uncertainties modify detector level acceptance. Sensitivity to particle level
1267 acceptance is calculated by comparing Pythia and Herwig. Finally, the bias from
1268 the IB prior choice is determined by reweighting the particle-level spectrum, so

1269 the simulated detector level spectrum more closely matches the uncorrected data.
 1270 Unfolding this modified detector-level simulation and comparing it re-weighted
 1271 particle-level spectrum indicates bias from the prior distribution choice.

1272 A summary of all the systematic uncertainties associated with this unfolding
 1273 may be found in [ref paper]. Total uncertainties are < 7% for the number of
 1274 charged particles in jets. The unfolded distribution of the nCharged in jets from
 1275 data are further analyzed to extract the quark and gluon nCharged distributions.
 1276 In dijet events, the jet with a larger η is more energetic and therefore more likely
 1277 to be a quark. This is due to the quarks in protons generally having a larger
 1278 fraction of the total momentum of the proton constituents. The more central jet
 1279 is more likely to be a gluon-initiated jet. This correlation between jet η and flavor
 1280 may then be used to extract nCharged in p_T bins using:

$$\langle n_c^f \rangle = f_q^f \langle n_c^q \rangle + f_g^f \langle n_c^g \rangle \quad (12.1)$$

$$\langle n_c^c \rangle = f_q^c \langle n_c^q \rangle + f_g^c \langle n_c^g \rangle \quad (12.2)$$

1282 In this equation the f and c subscripts denote the more forward and central
 1283 jets, respectively. The q and g subscripts denote quark and gluon. The fraction
 1284 of more forward jets that are say gluons is denoted by f_g^f . The other relevant jet
 1285 fractions are denoted with the same naming scheme. Finally, $\langle n_c \rangle$ is the average
 1286 number of charged particles in a jet in a given p_T bin. To show that Eq. (??) may
 1287 be used to extract quark and gluon n_c distributions the extracted distributions
 1288 are compared to n_c distributions determined using the jet flavor in simulation.
 1289 Figure [add figure natasha] shows that the extracted and true distributions differ
 1290 by < 1% over the p_T ranged probed for this study. Moreover, this implies that n_c
 1291 depends only on the flavor of the initiating parton and jet p_T .

1292 These extracted distributions are prone to PDF and ME biases. The bias from

1293 the choice of the CT10 PDF for the Pythia sample is accounted for by comparing
1294 quark/gluon fractions for the nominal CT10 sample with its eigenvector variations.
1295 Comparing the quark/gluon fractions from Pythia 8 and Herwig++ quantify the
1296 uncertainty from the ME calculation. These uncertainties are added in quadra-
1297 ture with the unfolding uncertainty to give the total modelling uncertainty on
1298 the extracted n_c distribution. This is shown in Figure 13.2.

1299 To apply these uncertainties in n_c distributions in data, per-jet event weights
1300 are associated with each uncertainty according to:

$$w_i(n_c) = \frac{P(n_c | < n_c > \pm \sigma_{n_c}^i)}{P(n_c | < n_c >)} \quad (12.3)$$

1301 In Eq. (??), i denotes the uncertainty considered, P is the Poisson probability,
1302 and $\sigma_{n_c}^i$ represents the average impact of the uncertainty on n_c .

1303 The previous uncertainties described accounted for modeling uncertainty as-
1304 sociated with the number of charged particles in a jet. However, n_c is not a
1305 measurable quantity. Instead the number of tracks in a jet is measured, which is
1306 a proxy for n_c . Therefore the uncertainties associated with the measurement of
1307 nTracks must also be considered ([9]). These uncertainties were calculated using
1308 a Pythia 8 dijet sample with NNPDF 23. Track reconstruction efficiency and fake
1309 rates are the dominant sources of nTrack uncertainties.

1310 The track reconstruction efficiency is effected by the uncertainty of the de-
1311 scription of the ID material in simulation and the modeling of charged-particle
1312 interactions with this material. These uncertainties are accounted for by varying
1313 the ID material by 5-25% (dependent on the region of the detector considered).
1314 The difference in the tracking efficiency between the nominal and varied simula-
1315 tion give the uncertainty on the track reconstruction efficiency. Another important
1316 source of track reconstruction efficiency arises in the core of jets. The high density

1317 of tracks in the jet cores can cause ID clusters to merge. The fraction of lost tracks
 1318 due to merging is given by the fraction of tracks that have a charge of two mini-
 1319 mum ionizing particles. This quantity is compared between data and simulation
 1320 resulting in an uncertainty of 0.4% on tracks with $\Delta R < 0.1$. Combining these
 1321 effects gives a total uncertainty as a function of p_T and η that is generally $< 2\%$
 1322 [references figure 44 from [9]).]

1323 Fake tracks are the other dominant source of nTrk uncertainty. Fake tracks
 1324 are tracks that cannot be associated to a single particle. Often these tracks are a
 1325 result of random combinations of hits from charged particles that overlap in space.
 1326 In dense environments, such as the core of jets or high-pileup environments, fake
 1327 tracks are more likely. Fake tracks are estimated with a 'control region method'
 1328 which is briefly summarized here [[8]]. By applying a series of track selections
 1329 to enrich the fraction of fake tracks (e.g. $|d_0| > 0.1$, track $\chi^2 > 1.4$, etc) in
 1330 simulation, templates for fake track parameters are calculated. These templates
 1331 are then fit to data to determine the fraction of fake tracks. On average the fake
 1332 rate is found to be 30% (independent of p_T and η).

1333 To assess the impact of these two detector level uncertainties, tracks are ran-
 1334 domly dropped according to the rates described above. Reconstruction and fake
 1335 uncertainties both lower the number of tracks, hence these uncertainties are one-
 1336 sided. By dropping tracks in this way a varied nTrk distribution is calculated for
 1337 both uncertainties. The associated per-jet event weights are then calculated in
 1338 the same way as the modeling weights as:

$$w_i(n_c) = \frac{P(n_{trk} | < n_{trk} > \pm \sigma_{n_{trk}}^i)}{P(n_{trk} | < n_{trk} >)} \quad (12.4)$$

1339 Adding the modeling and detector level uncertainties in quadrature gives the
 1340 overall nTrack uncertainty. The effects of the individual uncertainties on the nTrk

1341 distributions can be seen in Fig 13.4. Fig 13.3 shows the m_{lvqq} and nTrk distri-
1342 butions for the W and Top control regions before likelihood fitting. In these plots
1343 the nTrk uncertainties improve agreement between data and MC. The remaining
1344 differences are likely covered by likelihood fitting and improving the analysis itself.

₁₃₄₅ **Chapter 13**

₁₃₄₆ **Application**

₁₃₄₇ Using the 90% WP of the n_{trk} tagger improves S/\sqrt{B} is $< 3\%$ as shown in
₁₃₄₈ Figure 11.9. Although, n_{trk} is the single most powerful discriminating variable
₁₃₄₉ for quark and gluon jets, the addition of other jet variables would improve the
₁₃₅₀ classification efficiency. Figure 13.1 shows the possible improvement of 10%
₁₃₅₁ in jet classification using the truth label of the jets to classify jets. This type of
₁₃₅₂ improvement is possible by using variables such as jet width, and energy correlata-
₁₃₅₃ tors. Figure [add BDT figure/use 1612.01551.pdf] shows for a 90% quark tagging
₁₃₅₄ efficiency for a 100 GeV jet, a BDT improve the gluon rejection by 0.4. Once this
₁₃₅₅ tagger is calibrated it would improve the analysis sensitivity of this channel.

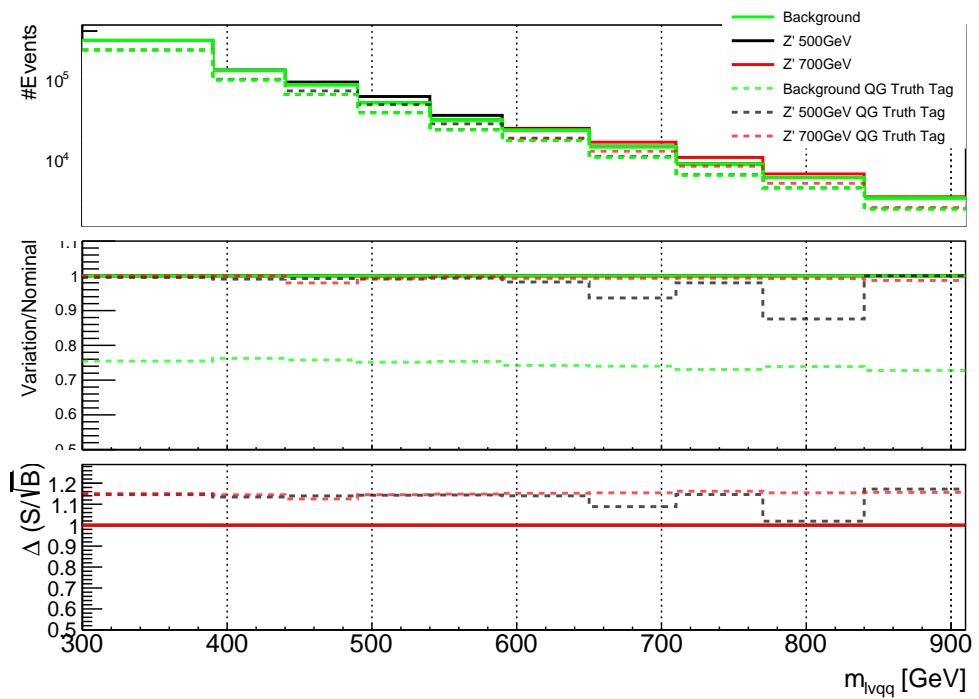

Figure 13.1: The top panel shows the distribution of m_{lvqq} with and without requiring jets to be true quarks. The middle panel shows the ratio of the signals and backgrounds with and without requiring jets to be true quarks. The bottom panel shows the change in S/\sqrt{B} when requiring jets to be true quarks..
